Federal Caucus. 2000. Conservation of Columbia basin fish. Final basinwide salmon recovery strategy (update of the All-H Paper). Prepared by the Federal Caucus (USACE, BPA, BIA, BLM, BOR, EPA, USFWS, USFS, NMFS). Volume 1: 87 pp. Volume 2: 179 pp. (Available from Northwest Fisheries Science Center, 2725 Montlake Blvd. E., Seattle, Washington 98112-2097.) Available online at: http://www.salmonrecovery.gov.

FERC (Federal Energy Regulatory Commission). 1953. Terms and conditions of license for unconstructed major project affecting navigable waters and lands of the United States (Rocky Reach hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued December 15, 1953.

---. 1957a. Order issuing license (Major). Project No. 2145 (Rocky Reach hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued July 11, 1957.

---. 1957b. Instrument No. 2, Amendment No. 1, Order amending license. Project No. 2145 (Rocky Reach hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued December 23, 1957.

---. 1962a. Federal Power Commission license, Project No. 2149 (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued July 12, 1962.

---. 1962b. Instrument No. 2, Amendment No. 1, Order amending license (Major). Project No. 2149 (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued September 18, 1962.

---. 1965. Order No. 313, Issuing statement of general policy, recreational development (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued December 27, 1965.

---. 1968. Instrument No. 10, Amendment No.5, Order further amending license (Major). Project No. 2145 (Rocky Reach hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued May 23, 1968.

---. 1970. Instrument No. 6, Order approving revised Exhibit L drawings (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued September 22, 1970.

---. 1975a. Terms and conditions of license for constructed major project affecting navigable waters and lands of the United States (Rock Island hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Revised October, 1975.

---. 1975b. Order approving settlement with modification (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued May 12, 1975.

---. 1976. Order approving Exhibit R. Project No. 2145 (Rocky Reach hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued March 2, 1976.

---. 1980. Appendix to application for amendment of major license. Douglas County Public Utility District, Project No. 2149-006.

---. 1982. Instrument No. 10, Amendment No. 20, Order amending license (Major) (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued September 23, 1982.

---. 1987a. Rock Island settlement agreement. Project No. 943. Docket No. E-9569. Public Utility District No. 1 of Chelan County, Wenatchee, Washington. Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued April 24, 1987.

---. 1987b. Interim stipulation for Rocky Reach project. Project No. 2145. Docket No. E-9569. Public Utility District No. 1 of Chelan County, Wenatchee, Washington. Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued November 20, 1987.

---. 1988. Final environmental impact statement, Rock Island hydroelectric project (FERC Number 943, Washington). Washington, D.C.

---. 1989a. Order on remand issuing license (major) and approving settlement agreement (Rock Island hydroelectric project). Project No. 943. Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued January 18, 1989.

---. 1989b. Instrument No. 12, Amendment No. 46, Order modifying license Article 41 (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued February 24, 1989.

---. 1990. Settlement agreement No. 2149, Docket No. E-9569. Public Utility District No. 1 of Douglas County, East Wenatchee, Washington.

---. 1991. Instrument No. 13, Amendment No. 54, Order approving settlement agreement (Wells hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued January 24, 1991.

---. 1993a. Order approving modification to adult fish mortality study (Rock Island hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Issued October 19, 1993.

---. 1993b. Staff report Volume 1. Glines Canyon (FERC No. 588) and Elwha (FERC No. 2683) hydroelectric projects, Washington.

---. 1995. Rocky Reach project No. 2145, Docket Nos. E-9569 et al. Rocky Reach fourth interim stipulation. Public Utility District No. 1 of Chelan County, Wenatchee, Washington. Federal Energy Regulatory Commission, Washington, D.C.

---. 1996a. Rocky Reach project fourth revised interim stipulation (Rocky Reach hydroelectric project). Office of Hydropower Licensing, Federal Energy Regulatory Commission, Washington, D.C. Received by Steptoe & Johnson LLP April 26,1996.

---. 1996b. Final environmental impact statement, Rocky Reach hydroelectric project (FERC No. 2145, Washington). Washington, D.C.

---. 1999. Revised List of Comprehensive Plans. Federal Energy Regulatory Commission, Office of Energy Projects, Washington, D.C. Available at: http://www.ferc.fed.us/hydro/docs/complan.pdf.

Glossary

CHANGES MADE BETWEEN THE DEIS AND FEIS FOR CHAPTER 7

- Additional terms were added, including those used for economics.

Chapter

7 GLOSSARY

303(d) list – A list of water bodies that the WDOE has identified as having impaired water quality based on evidence that specific water quality standards have not been met. Section 303(d) of the Federal Clean Water Act requires that states prepare and periodically update these lists and develop controls to bring the water bodies into compliance with standards and protect beneficial water uses (e.g., water supply, cold-water fisheries).

Adaptive Management – The process of monitoring the implementation of conservation measures, then adjusting future conservation measures according to what was learned. Adaptive management can also include testing of alternative conservation measures, monitoring the results, and then choosing the most effective and efficient measures for long-term implementation.

Alevin – The life stage of salmonids between hatching and active feeding when the yolk sac is still present, generally equivalent to sac fry or larval stage.

aMW – Average megawatts per hour for every hour in the period from March through September for this project.

Anadromous – Describes the life-history characteristic of a fish species that reproduces in freshwater, migrates to the ocean for some portion of its rearing stage, and returns to freshwater as an adult.

Aquatic Macrophytes – Plants that occur entirely immersed within or under water.

Artificial Supplementation – Hatchery programs that are used to enhance natural reproduction in the natural environment.

Basalt – A fine-grained, igneous rock dominated by dark-colored minerals. Cliffs along the Columbia River Valley are typically formed in basalt.

Base Flow – The normal low flow that occurs seasonally in a river or creek. During a period of run-off from rain or snowmelt, streams rise above base flow levels and then recede to base flows sometime after the runoff event has passed. Base flows are sustained by groundwater discharges or snowmelt that may vary seasonally (e.g., higher base flow in the spring and lower in the summer).

Biological Assessment – A requirement under the Endangered Species Act, to assess the effects of a Federal action on a Federally listed threatened or endangered species. A biological assessment report is prepared by the project proponent and provides existing and projected conditions that affect a threatened or endangered species and the proposed mitigation measures that minimize or avoid impacts to these species.

Biological Opinion – An opinion from USFWS or NMFS as to the effects of a Federal action on a Federally listed threatened or endangered species. A biological opinion is a report that reviews and considers the adequacy of the biological assessment that is initially prepared by the project proponent. The biological opinion includes conservation measures recommended by the agency to protect the listed species.

Biological Productivity – Capacity of an ecological system to produce or support a particular population size of an animal (fish) or plant species.

Broodstock – Group of fish that are used to provide eggs and sperm to produce a hatchery stock for supplementation purposes.

Bypass System – Structure in a dam that provides a route for fish to move through or around the dam without going through the turbines. See also Juvenile Bypass.

Candidate Species – As defined by the USFWS and NMFS, candidate species are wildlife, fish, or plants being considered for listing as endangered or threatened, but for which more information is needed before they can be proposed for listing.

Channel Structure – Channel structure is formed by river bed roughness elements like bars and bends, in-channel logs or debris jams, bank vegetation, and large rocks. Channel structure is important for channel flow velocities, aquatic habitat, and preventing channel erosion.

Columbia Plateau – Relatively flat region of eastern Washington and northern Oregon formed by vast accumulations of near horizontal flows of basalt lava.

Conservation Measures – Actions that a non-Federal property owner voluntarily agrees to undertake when preparing a habitat conservation plan.

Covered Species – Species that have been adequately addressed in an HCP as though they were listed, and are therefore included on the permit or, alternatively, for which assurances are provided by the permittee that such species will be added to the permit if listed under certain circumstances. Covered species are also subject to the assurances of the No Surprises policy. Also referred to as ***Plan species***.

Critical Habitat – Specific areas occupied by a species that contain physical and biological features essential to the conservation of the species, and which may require special management considerations for protection. These areas might provide space for individual or population growth, nutritional or physiological requirements, breeding and rearing habitat, or shelter or cover for protection, or they might represent the historical or geographical distribution of the species.

Cultural Resource – Nonrenewable evidence of human occupations or activity as seen in any district, site, building, structure, artifact, ruin, object, work of art, architecture, or natural feature associated with the cultural practices or beliefs of a living community.

Cumulative Impact or Effect – Under NEPA regulations, the incremental environmental impact or effect of the action together with the impacts of past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such other actions (40 CFR 1508.7). Under Endangered Species Act Section 7 regulations, the effects of future State or private activities not involving Federal activities, that are reasonably certain to occur within the action area of the Federal action subject to consultation (50 CFR 402.02).

Dam – A structure impounding a river.

Delist – To remove from the Federal list of endangered and threatened species (50 CFR 17.11 and 17.12) because such species no longer meets any of the five listing factors provided under Section 4(a)(1) of the Endangered Species Act and under which the species was originally listed (i.e., because the species has become extinct or is recovered).

Dissolved Oxygen – The amount of oxygen that is in a solution of water.

Drawdown – The distance that the water surface of a reservoir is lowered from a given elevation as water is released from the reservoir. Also refers to the act of lowering reservoir levels.

Effect or Impact – Under NEPA regulations, a direct result of an action that occurs at the same time and place; or an indirect result of an action that occurs later in time or in a different place and is reasonably foreseeable; or the cumulative results from the incremental impact of the action when added to other past, present and reasonably foreseeable future actions regardless of what agency or person undertakes such other actions (40 CFR 1508.8). Under Endangered Species Act Section 7 regulations, "effects of the action" means "direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action, that will be added to the environmental baseline" (50 CFR 402.02).

Embankment – The earthen portion of a dam that is typically filled in after the concrete portion is built to form the reservoir.

Endangered Species – A species of plant, fish, or wildlife which is in danger of extinction throughout all or a significant portion of its range.

Endangered Species Act – The Endangered Species Act of 1973, 16 USC §§ 1531 through 1543, as amended and its implementing regulations. Federal legislation which provides a means to ensure the continued existence of threatened or endangered species and the protection of critical habitat of such species.

Environmental Impact Statement – A detailed written statement required by Section 102(2)(C) of NEPA containing, among other things, an analysis of environmental impacts of a proposed action and alternatives considered, adverse effects of the project that cannot be avoided, alternative courses of action, short-term uses of the environment versus the maintenance and enhancement of long-term productivity, and irreversible and irretrievable commitment of resources (40 CFR 1508.11 and 40 CFR 1502).

Evolutionarily Significant Unit – A reproductively isolated animal or fish population that represents an important component in the ecological/genetic diversity evolution of the species. The unit typically has a relatively confined historical or geographical distribution. To be considered an Evolutionarily Significant Unit, a population must satisfy two criteria: (1) it must be reproductively isolated from other population units of the same species, and (2) it must represent an important component in the evolutionary legacy of the biological species. The first criterion, reproductive isolation, need not be absolute but must have been strong enough to permit evolutionarily important differences to occur in different population units. The second criterion is met if the population contributes substantially to the ecological or genetic diversity of the species as a whole.

Fallback – Adult fish that successfully pass upstream of a dam, but are either swept or swim through the spillway, turbines, or navigation locks to below the dam.

FERC License – A Federal license for hydroelectric projects that includes requirements and restrictions about how the projects are maintained and operated. The PUD hydroelectric projects are licensed by FERC under the Federal Power Act.

First Year Value – First year value is the cost and foregone power revenues incurred in the first year of the 50-year analysis period.

Fishladder – A series of ascending pools constructed to enable salmon or other fish to swim upstream to pass a barrier.

Fish Passage Efficiency – The portion of all juvenile salmon and steelhead passing a facility that do not pass through the turbines.

Fish Passage Facilities – The features of a dam that enable fish to move around, through, or over a dam without harm. Facilities generally include an upstream fishladder and/or a downstream bypass system. See also ***Fishladder*** and ***Bypass System***.

Flow (or Discharge) – A measurable quantity of water passing through a dam or a reach of river over a given period of time. Flows for rivers in the United States are commonly reported in cubic feet per second (cfs).

Fluvial – Related to rivers or produced by river action, as a fluvial plain or river bar.

Forebay – The portion of the reservoir at a hydroelectric plant which is immediately upstream of the generating station.

Fry – Life stage of fish between the egg and fingerling stages. For salmon this typically refers to fish less then 50 millimeters long.

Gas Bubble Disease – Condition caused when dissolved gas in supersaturated water comes out of solution and equilibrates with atmospheric conditions, forming bubbles within the tissue of aquatic organisms. Gas bubble disease is also known as gas bubble trauma or GBT.

Gas Supersaturation – Concentrations of dissolved gas in water that are above the saturation (100 percent capacity) level of the water.

Geomorphology – Branch of geology that deals with the form of the earth and earth surface and the changes that take place in river and hillside landforms.

Glacial – Related to or formed by a glacier. Extensive glaciers flowed into the Mid-Columbia River area, greatly influencing the river and valley landforms and geologic deposits.

Gneiss – Coarse-grained, metamorphic rock in which bands of differing mineral composition and texture appear.

Graben – An elongate, trench-like structural form bounded by parallel faults, created when the block that forms the valley floor moved downward relative to the blocks that form the valley wall sides.

Habitat – The location where a particular taxon of plant or animal lives and its surroundings; the term includes the presence of a group of particular environmental conditions surrounding an organism including air, water, soil, mineral elements, moisture, temperature, and topography.

Habitat Conservation Plan (HCP) – Under Section 10 (a)(2)(A) of the Endangered Species Act, a planning document that is a mandatory component of an incidental take permit application. The HCP process is intended to provide a comprehensive, long-term management plan to protect and facilitate the recovery of threatened and endangered species, and to provide a framework for "creative partnerships" between the public and private sectors in endangered species conservation (H.R. Rep. No. 97-835, 97th Congress, Second Session).

Habitat Improvement – Management of wildlife or fish habitat to increase its capability for supporting wildlife or fish.

Harass – Defined in regulations implementing the Endangered Species Act promulgated by the Department of the Interior as "an intentional or negligent act or omission which creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding, and sheltering" (50 CFR17.3). NMFS has not defined "harass" by regulation.

Harm – Defined in regulations implementing the Endangered Species Act promulgated by the Departments of Interior and Commerce as an act "which actually kills or injures" listed fish or wildlife; harm may include "significant habitat modification or degradation where it actually kills or injures fish or wildlife by significantly impairing essential behavioral patterns, including breeding, spawning, rearing, migrating, feeding, or sheltering" (50 CFR 17.3 and 50 CFR 222.102).

Hatchery – A facility in which fish eggs are incubated and hatched and juvenile fish are reared for release to rivers or lakes.

Headwater Elevation – The average or maximum reservoir elevation at the project dam.

Historic Integrity – The extent to which a property has retained its original design and setting.

Historic Property – A property listed on the National Register of Historic Places.

Hydroelectric – Referring to the production of electric power through use of the gravitational force of falling water.

Hydrology – The science of the continuous cycle of evapotranspiration, precipitation, and run-off.

Incidental Take – Take of any Federally listed fish, wildlife, or plant species that is incidental to, but not the purpose of, otherwise lawful activities. See definition for ***take*** [Endangered Species Act Section 10(a)(1)(B)].

Incidental Take Permit – A permit that exempts a permittee from the take prohibition of Section 9 of the Endangered Species Act, provided that a conservation plan has been developed that specifies the likely take and steps that the

applicant will use to mitigate and minimize the take. An incidental take permit is issued by USFWS or NMFS under Section 10 of the Endangered Species Act for non-Federal applicants.

Incidental Take Statement – An incidental take statement is issued under Section 7 of the Endangered Species Act for projects that involve a Federal action. The statement identifies the extent of the take that would occur as a result of the action, as well as reasonable and prudent measures to minimize the take.

Instream Flow – The amount of water in a river or creek required to sustain fisheries and water quality needs.

Intake – The entrance to a conduit through a dam or water facility.

Juvenile – The early stage in the life cycle of anadromous fish when they migrate downstream.

Juvenile Bypass – Facility that is used to collect, divert or guide juvenile fish around a dam that provides a safer passage route than through the turbine units. See also ***Bypass System***.

Kelts – Adult steelhead that have completed spawning and are returning to the ocean. Steelhead can spawn more than once in their lifetime.

Levelized Value – A constant stream of values, using a given interest rate, that produces the same net present value as the non-constant stream of values (if future values change over time).

Listed Species – Wildlife, fish, or plants that are identified as either threatened or endangered within a region, state, or nation. Federally listed species are listed by USFWS or NMFS and consequently receive statutory protection throughout areas where their populations are in decline under the Endangered Species Act.

Measures – Any action, structure, facility, or program (on-site or off-site) intended to improve the survival of Plan species.

Mid-Columbia River – When used in reference to a geographic area, it means that portion of the Columbia River that begins at its confluence with the Yakima River up to the Chief Joseph Dam. It may also be used to reference the Mid-Columbia River Evolutionarily Significant Unit. See also ***Upper Columbia River*** and ***Mid-Columbia River Steelhead Evolutionarily Significant Unit***.

Mid-Columbia River Steelhead Evolutionarily Significant Unit – The ESU includes all naturally spawned populations of steelhead in streams from above the Wind River, Washington, and the Hood River, Oregon (exclusive), upstream to, and including, the Yakima River, Washington. Excluded are steelhead from the Snake River Basin.

Mitigation – Measures designed to counteract environmental impacts or make impacts less severe. These measures may include amending an impact by not taking a certain action or part of an action; minimizing an impact by repairing, rehabilitating, or restoring the affected environment; reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action; or compensating for the impact by replacing or providing substitute resources or environment.

Monitoring – HCP monitoring consists of two types: (1) compliance monitoring, in which NMFS monitors the permittee's implementation of the requirements of the HCP, incidental take permit terms and conditions and implementation agreement, if applicable; and (2) effects and effectiveness monitoring, in which the permittee (or other designated entity) examines the impacts of the authorized incidental take (effects) and implementation of the operating conservation program to determine if the actions are producing the desired results (effectiveness).

National Environmental Policy Act (NEPA) – Federal legislation establishing national policy that environmental impacts will be evaluated as an integral part of any major Federal actions significantly affecting the quality of the human environment (42 USC §§ 4321-4327).

National Register of Historic Places – The official Federal list of districts, sites, buildings, structures, and objects significant in American history, architecture, archaeology, engineering, and culture.

Net Present Value – Discounted value today of the future values using a given discount rate.

No Net Impact – The objective of the HCPs is to achieve 100 percent no net impact for each Plan species affected by the Wells, Rocky Reach, and Rock Island hydroelectric projects. The no net impact standard consists of two primary components: 91 percent combined juvenile and adult project passage survival achieved by project improvement measures implemented within the geographic area of the projects, and a 9 percent compensation for unavoidable project mortality. The utilities would compensate for the 9 percent fish loss at the projects through a hatchery and tributary habitat fund. Hatcheries would compensate for 7 percent of fish mortality at the projects. Habitat improvements in the Mid-Columbia River tributaries would compensate for the remaining 2 percent mortality. This compensation for project mortality would result in a no net impact standard at the three projects.

No Surprises Policy – A policy of NMFS and USFWS providing regulation assurances for an HCP incidental take permit holder that no additional land use restrictions or financial compensation would be required with respect to species covered by the permit, even if unforeseen circumstances arise after the permit is issued that indicate additional mitigation is needed to protect the species.

Noxious Weeds – These weeds are non-native plants that have been introduced to Washington. Noxious weeds can be destructive and competitive with native plants, and difficult to control by cultural or chemical practices. These exotic species can reduce crop yields, replace native plant and animal habitat, affect land values and recreational opportunities, and infiltrate waterways.

Old-Growth Forest – A forest stand characterized by trees well past the age of maturity (dominant trees exceed 200 years of age). Stands exhibit declining growth rates and signs of decadence, such as dead and dying trees, snags, and downed woody material.

Performance criteria – Standards used to determine the adequacy of the mitigation and conservation measures implemented to protect the species.

Permit – An incidental take permit issued to the PUD pursuant to Section 10(a)(1)(B) of the Endangered Species Act to authorize any incidental take of listed species which may result from the PUD's otherwise lawful operation of the project, conducted in accordance with this agreement.

Permit species – For the purposes of this EIS, Permit species are all Plan species except coho salmon (*Oncorhynchus kisutch*). Permit species do not include coho salmon since wild coho salmon are extirpated from the Mid-Columbia region and therefore not protected by the Endangered Species Act.

Physiographic Regions – Areas with similar landforms, geologic materials, soils, and climate.

PIT-Tag – A Passive Integrated Transponder tag (about the size of a grain of rice) transmits a digital code, unique to an individual fish, when the tagged animal passes through a detection tunnel. The tag uses the power emitted by the detection system to transmit the signal, thus it has no batteries (making it functional for years). The tag is typically used on juvenile fish to assess passage survival, as well as to track adult passage rates.

Plan Species – For the purposes of this EIS, Plan species are spring-run and summer/fall-run chinook salmon (*Oncorhynchus tshawytscha),* sockeye salmon (*O. nerka*), coho salmon (*O. kisutch*), and steelhead (*O. mykiss*).

Powerhouse – Section of a dam that contains the turbine units to generate electricity.

Priority Habitats (as designated by WDFW) – Priority habitats are those habitat types or elements with unique or significant value to a diverse assemblage of species. A priority habitat may consist of a unique vegetation type or

dominant plant species, a described successional stage, or a specific structural element.

Project – (1) Refers to the Anadromous Fish Agreements and Habitat Conservation Plans Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island hydroelectric projects, or (2) refers to an individual hydroelectric project (reservoir, forebay, dam, and tailrace).

Proposed Action – Under NEPA regulations, a plan that has a goal which contains sufficient details about the intended actions to be taken or that will result, to allow alternatives to be developed and its environmental impacts to be analyzed (40 CFR 1508.23).

Proposed Species – A species for which a proposed rule to add the species to the Federal list of threatened and endangered species has been published in the Federal Register.

Quantitative Analysis Report (QAR) – The Upper Columbia QAR process was established to provide decision makers with current assessments of the status of Endangered Species Act-listed spring-run chinook salmon and steelhead runs returning to the Upper Columbia River. Simple population models were developed for Upper Columbia River spring-run chinook salmon (Wenatchee, Entiat, and Methow populations) and summer steelhead (Wenatchee/Entiat and Methow populations). The models are based on reconstructed spawner to spawner return ratios for historical years. Alternative assumptions regarding the effectiveness of hatchery-origin spawners are considered in the analysis for steelhead, and a range of future environmental conditions were analyzed for spring-run chinook. A range of alternative future survival improvements for Upper Columbia River stocks were modeled, including an analysis of the expected survival improvements that could be expected from implementation of the long-term mitigation measures outlined in the Chelan and Douglas County PUD HCPs.

Radio-telemetry – Methodology consisting of attaching or implanting a radio tag in a fish or animal to track its movements or to detect its presence in specific areas that are monitored with a radio receiver and antenna.

Record of Decision (ROD) – Under NEPA regulations, a concise public record of decision prepared by the Federal agency, pursuant to NEPA, that contains a statement of the decision, identification and discussion of all factors used by the agency in making its decision, identification of all alternatives considered, identification of the environmentally preferred alternative, a statement as to whether all practical means to avoid or minimize environmental harm from the alternative selected have been adopted (and if not, why they were not), and a summary of monitoring and enforcement measures, where applicable, for any mitigation (40 CFR 1505.2).

Redd – Depression in river or lake bed dug by fish for the deposition of eggs (spawning nests).

Reservoir – An artificially impounded body of water.

Resident – Describes the life-history characteristic of a fish species that spends its entire life in freshwater.

Riparian Vegetation – Riparian zones are broadly defined as those non-aquatic areas contiguous with waterbodies (wetlands, lakes, streams, and rivers) that are influenced by, and which influence, that waterbody. Often riparian zones exhibit higher plant and animal diversity and productivity than surrounding uplands, and are particularly important to fish and wildlife in arid regions. Riparian vegetation may or may not be distinct from the adjacent upland vegetation.

Rip-rap – Broken rock, cobbles, or boulders placed on the bank of a stream or river for protection against the erosive action of water.

River Terrace – Relatively flat areas formed by the rivers. Terraces near the rivers are active floodplains; higher terraces have been abandoned by river downcutting and are no longer accessed by flood flows. Floodplain terraces are common locations for wetlands and side channels, and are important areas for storage of floodwaters and aquatic and wildlife habitat.

Run-of-the-River Hydroelectric Project – The Wells, Rocky Reach, and Rock Island hydroelectric projects are run-of-the river projects, which means that they do not store substantial amounts of water in their reservoirs. Run-of-the-river hydroelectric projects produce electric power through use of the gravitational force of falling water, and consist of a powerhouse, spillway, and embankments, as well as fish passage facilities.

Salmonids – Fish of the family Salmonidae, such as salmon, trout (including steelhead), char, and whitefish.

Schist – Medium- or coarse-grained, metamorphic rock dominated by subparallel orientation of platy mica minerals.

Scoping – The process of defining the scope of a study, primarily with respect to the issues, geographic area, and alternatives to be considered. The term is typically used in association with environmental documents prepared under NEPA.

Section 10 – The section of the Endangered Species Act dealing with exceptions to the prohibitions of Section 9 of the Endangered Species Act.

Section 10(a)(1)(A) – That portion of Section 10 of the Endangered Species Act that allows for permits for the taking of threatened or endangered species for scientific purposes or for purposes of enhancement of propagation or survival.

Section 10(a)(1)(B) – That portion of Section 10 of the Endangered Species Act that allows for permits for incidental taking of threatened or endangered species.

Section 10(a)(2)(A) – That portion of Section 10 of the Endangered Species Act that identifies the requirements of a habitat conservation plan.

Section 10(a)(2)(B) – That portion of Section 10 of the Endangered Species Act that identifies the findings that must be made in order to issue an incidental take permit based upon the habitat conservation plan.

Section 106 of the Historic Preservation Act – A Federal regulation that requires properties with Federal involvement to take into consideration impacts to properties listed in or eligible for the National Register.

Section 4(d) – Section of the Endangered Species Act that allows NMFS or USFWS to adopt whatever protective regulations it deems necessary for the conservation of a threatened species. This section does not apply to endangered species.

Section 7 – The section of the Endangered Species Act which describes the responsibilities of Federal agencies in conserving threatened and endangered species. Section 7(a)(1) requires all Federal agencies "in consultation with and with the assistance of the Secretary [to] utilize their authorities in the furtherance of the purposes of this Act by carrying out programs for the conservation of endangered species and threatened species." Section 7(a)(2) requires Federal agencies to "ensure that any action authorized, funded, or carried out by such agency…is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of…" designated critical habitat.

Section 9 – The section of the Endangered Species Act dealing with prohibited acts, including the take of any listed species without the specific authorization of USFWS or NMFS for species under the jurisdiction of each agency.

Sediment – Clay, silt, sand, gravel, and cobbles that are deposited into layers by wind, ice, water, or gravity.

Settlement Agreement – An agreement that settles a legal dispute. In the context of this EIS, relevant settlement agreements are the 1990 Wells Long-Term Settlement Agreement, the 1994 Fourth Revised Rocky Reach Interim Stipulation (expired), the 1987 Rock Island Settlement Agreement, and the Vernita Bar Agreement. In addition, the Wells, Rocky Reach, and Rock Island HCPs are also settlement agreements that are expected to supercede all of the above agreements, except for the Vernita Bar Agreement.

Signatory Parties – For the purposes of this EIS, signatory parties refers to those agencies, tribes, and non-governmental organizations that will ultimately sign and abide by the terms of the HCPs. As a result, each of the signatory parties will be represented on the HCP committees.

Sluice – A spill gate specifically designed to drain water from the surface of the reservoir.

Smolt – A juvenile salmon or steelhead migrating to the ocean and undergoing physiological changes to adapt its body from a freshwater to a saltwater environment.

Spawning – The releasing and fertilizing of eggs by fish.

Species –any subspecies of fish or wildlife or plants and any distinct population segment of any species of vertebrate fish or wildlife that interbreeds when mature.

Spill – Water passed over a spillway instead of going through turbines to produce electricity. Spill can be forced when there is no storage capacity and flows exceed turbine capacity, or it can be planned, for example, when water is spilled to enhance juvenile fish passage.

Spillway – The overflow structure of a dam.

State Environmental Policy Act (SEPA) – Chapter 43.21C RCW. Enacted in 1971, it provides the framework for agencies to consider the environmental consequences of a proposal before taking action. It also gives agencies the ability to condition or deny a proposal due to identified likely significant impacts. The Act is implemented though the SEPA Rules, Chapter 197-11 WAC.

Steering Committee – Group or panel of individuals representing affected interests or stakeholders in a conservation planning program, the private sector, and the interested public, which may be formed by the appropriate development, land use, and mitigation strategies, and to communicate progress to their larger constituencies. USFWS and NMFS representatives may participate to provide information on procedures, statutory requirements, and other technical information.

Storage Reservoir – A reservoir that has space for retaining water from springtime snowmelts. Retained water is released as necessary for multiple uses—power production, fish passage, irrigation, and navigation.

Structural Depression – Valley area formed by geologic faulting.

Subyearlings – Juvenile fish less than 1 year old.

Tailrace – The canal or channel that carries water away from a dam.

Tailwater Elevation – The average or minimum water elevation at the toe of the dam.

Take – Under Section 3(18) of the Endangered Species Act, "…to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct" with respect to Federally listed endangered species of wildlife. Federal regulations provide the same taking prohibitions for threatened wildlife species [50 CFR 17.31(a)].

Threatened Species – Any species designated under the Endangered Species Act that "is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range" [Section 3(19) of the Endangered Species Act].

Tool – For the purposes of this EIS, tool means any action, structure, facility or program (on-site only) at the Wells, Rocky Reach, and Rock Island dams that are intended to improve the survival of Plan species migrating through the dams. Tools do not include fish transportation, drawdowns, dam removal, and non-power operations.

Total Dissolved Gas – Total dissolved gas is the amount of all gases that are in solution (e.g., nitrogen, carbon dioxide, oxygen).

Tributaries – Smaller streams or rivers that enter larger water bodies. For example, the Wenatchee

River is a tributary of the Columbia River and Icicle Creek is a tributary of the Wenatchee River.

Turbidity – A measure of the cloudiness or opaqueness of water. In other words, muddy water has high turbidity and clear water has low turbidity. Turbidity is measured by an instrument that passes a beam of light through a water sample and measures the degree to which the light is scattered by suspended particles.

Turbine – Machinery that converts kinetic energy of a moving fluid, such as falling water, to mechanical or electrical power.

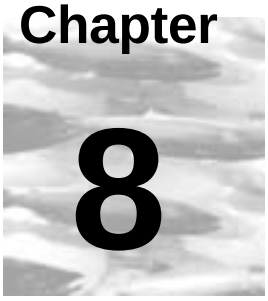
Upper Columbia River – When used in reference to a geographic area, it means that portion of the Columbia River upstream of Chief Joseph Dam. It may also be used to reference the Upper Columbia River Evolutionarily Significant Unit. See also ***Upper Columbia River Spring-Run Chinook Salmon Evolutionarily Significant Unit*** and ***Mid-Columbia River***.

Upper Columbia River Spring-Run Chinook Salmon Evolutionarily Significant Unit – This Evolutionarily Significant Unit contains the only remaining genetic resources of those spring-run chinook salmon that migrated into the Upper Columbia River basin (prior to the construction of Grand Coulee Dam), as well as those spring-run chinook salmon that historically migrated to the Mid-Columbia River region. NMFS also identified six hatchery stocks associated with the Upper Columbia River spring-run Evolutionarily Significant Unit: Chiwawa River, Methow River, White River, Twisp River, Chewuch River, and Nason Creek.

Water Quality Standards – Define the minimum requirements to protect beneficial uses of rivers, creeks, lakes, and other waterbodies and are required by the Federal Clean Water Act for all states to establish and enforce. The current Water Quality Standards for Surface Waters of the State of Washington (Chapter 173-201A of the Washington Administrative Code) designate water bodies as "Class AA" (extraordinary), "Class A" (excellent), or other classes. Each class has numerical and narrative standards to protect general beneficial uses, with Class AA having the most stringent standards. In the future the standards will be changed to identify specific beneficial uses for each waterbody. Similar to State standards, Tribes administer water quality standards on their lands.

Water Rights – Water rights permits are required from WDOE to withdraw water from rivers, creeks, and lakes, and may be required for groundwater resources. These permits specify where, when, and how much water may be withdrawn.

Wetlands – Areas that are inundated by surface water or groundwater frequently enough to support vegetation that requires saturated or seasonally saturated soil conditions for growth and reproduction. Wetlands generally include marshes, bogs, peatlands, and similar areas such as river overflows, mudflats, and natural ponds.



Distribution List

CHANGES MADE BETWEEN THE DEIS AND FEIS FOR CHAPTER 8

- The mailing list was revised, updated, and now includes addresses for all individuals and organizations who provided comment letters on the DEIS.

List of Preparers

CHANGES MADE BETWEEN THE DEIS AND FEIS FOR CHAPTER 9

- Additional FEIS project staff were added.

Chapter

9 LIST OF PREPARERS

The Anadromous Fish Agreements and Habitat Conservation Plans FEIS for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects was prepared by a team of specialists from a wide range of disciplines. The primary team members are listed below.

NAME	BACKGROUND	EXPERIENCE
Ritchie Graves Lead Biologist National Marine Fisheries Service, Portland, Oregon	M.A., Zoology, University of Montana B.S. Biology, Centre College of Kentucky B.S. English, Centre College of Kentucky National Marine Fisheries Service – 9 years Montana Department of Fish, Wildlife and Parks - < 1 year	Experience includes 4 years as a project biologist for the Smolt Monitoring Program at John Day Dam on the Lower Columbia River followed by 5 years of experience evaluating and addressing the effects of mainstem Federal and non-Federal hydroelectric projects on the Columbia and Snake rivers.
Pam Gunther Project Manager Parametrix, Inc., Kirkland, Washington	M.A., Biology, California State University B.S., Wildlife (Forest Resources), University of Washington Parametrix – 10 years U.S. Forest Service – 7 years Ebasco Environmental – 2 years EA Engineering – 2 years	Experience includes more than 18 years in the organization and oversight of environmental impact statements, with expertise in long-range planning and management of natural and biological resources.
Bob Sullivan Fisheries Task Leader Parametrix, Inc., Kirkland, Washington	B.S., Fisheries, University of Washington Parametrix – 16 years Quinault Indian Nation – 5 years	Nineteen years of consulting and research experience on fish habitat assessment and enhancement projects, which includes work evaluating bypass options, total dissolved gas levels, and methods to reduce total dissolved gas at Mid-Columbia hydroelectric projects.
Jim Good Water Resources Task Leader Parametrix, Inc., Kirkland, Washington	M.S., Aquatic Ecology, University of Idaho B.S., Forest Management, University of Missouri Parametrix – 14 years	Experience includes 13 years working with water quantity and quality and sediment issues and pertinent regulations. Other related experience includes hydrology and fish habitat assessments in National Forests with Idaho, Washington, Oregon, and Alaska.
Gary Maynard, AICP Land Use Task Leader Parametrix, Inc., Kirkland, Washington	M.A. Candidate, Geography, University of Washington B.A., Geography, University of Washington Parametrix – 13 years City of Bellevue – 3 years	Experience includes 13 years in land use, energy, natural resources, public services, and noise evaluations, analysis, and management.

NAME	BACKGROUND	EXPERIENCE
Marcia Montgomery Cultural Resources Task Leader Historical Research Associates, Seattle, Washington	M.A., History, Washington State University B.A., History, Lewis and Clark College Historical Research Associates – 3 years BOAS, Inc – 2 years National Park Service– 1 year U.S. Forest Service – 1 year	Experience includes 7 years of experience conducting cultural resource assessments of historic buildings, structures, and archaeological sites and addressing cultural resources according to Section 106 of the Historic Preservation Act, NEPA.
Clay Antieau Plants Task Leader Parametrix, Inc., Kirkland, Washington	Ph.D. Candidate, Horticulture and Botany, University of Washington M.S., Horticulture and Botany, University of Washington B.S., Horticulture, Purdue University Parametrix – 3 years Gaynor Landscape Architects – 3 years Foster Wheeler – 5 years WSU Cooperative Extension – 2 years	Experience includes more than 14 years as a botanist in western Washington specializing in identification and ecology of Pacific Northwest native plants and their habitats. Work includes conducting rare plant and wildlife surveys at hydroelectric projects.
David Mattern, AICP Socioeconomics and Recreation Task Leader Parametrix, Inc., Kirkland, Washington	M.A., Geography, University of Colorado B.S., Geography, University of Washington Parametrix – 18 years	Experience includes more than 16 years in environmental planning with responsibilities in EIS recreation analysis, planning policy evaluations, and land use, visual quality, and public service assessments. Work includes research and reports on land use, visual quality, and recreation for hydroelectric projects.
Julie Grialou Wildlife Task Leader Parametrix, Inc., Kirkland, Washington	M.S., Wildlife Science, University of Washington B.A., Anthropology, Harvard University Parametrix – 4 years Pacific Forest Trust – 2 years Bureau of Land Management – 2 years	Experience includes more than 7 years of work with threatened and endangered wildlife species, habitat evaluations, populations studies, vegetation surveys, and preparation of associated reports.
Bruce Stoker Geology Task Leader Earth Systems, Monroe, Washington	M.S.E., Civil Engineering, University of Washington M.S., Remote Sensing/Geology, University of Michigan B.S., Geology, Michigan State University Earth Systems – 6 years Ebasco Environmental – 9 years U.S. Forest Service – 1 year	Experience includes 19 years in geologic mapping, sediment transport studies, erosion control plans, hydrologic investigations, engineering review, licensing and permitting, and compliance with regulations related to project design.

NAME	BACKGROUND	EXPERIENCE
Jill Czarnecki Project Assistant Parametrix, Inc., Kirkland, Washington	B.S., Geology, University of Puget Sound Parametrix – 2 years	Experience includes 2 years in the organization and preparation of environmental impact statements.
Becky Reininger Aesthetics Task Leader Project Assistant Parametrix, Inc., Kirkland, Washington	M.A., Geography, University of Washington B.A., Environmental Planning, Huxley College at Western Washington University Parametrix – 2 years Pacific International Engineering – 2 years Harza NW/Hosey & Associates – 6 years	Experience includes 10 years in the organization and preparation of environmental documents including EAs, EISs, and FERC License applications.
Daryl Wendle Senior Planner Parametrix, Inc., Kirkland, Washington	M.A., English, New York University B.A., English, University of Oregon Parametrix – 4 years DKS Associates – 3 years KJS Associates – 3 years Beak, Inc. – 2 years	Experience includes 12 years preparing regional transportation planning and environmental impact studies.
Linda Goetz Cultural Resource Specialist Historical Research Associates, Seattle, Washington	Anthropology Graduate Program (1990-1993), University of Washington B.A., Anthropology, Northwestern University Historical Research Associates – 7 years Dames and Moore – 1 year	Experience includes 9 years in archaeological survey, excavation, and analysis. Other related work includes conducting background research, mapping, processing and cataloging archaeological materials, conducting Indian consultation, and writing and editing professional reports.
Lorena Dinger Technical Editor Parametrix, Inc., Kirkland, Washington	Technical Editing Certification Program, Bellevue Community College Parametrix – 2 years Freelance writer/editor – 3 years	Experience includes over 5 years of technical writing and editing experience, 2 years of which focused on preparation of NEPA environmental assessments and environmental impact statements and other environmental documents.

Presentation Part I

Question: Can you explain a little bit about how the relationship of the Biological Opinion that they are operating under now dovetails into the adoption of the HCPs to get some consistencies ….. ?

Bob Dach: There are sort of two related issues that you are thinking about: (1) what's going on in the interim the species were listed in 1997 and 1998 and here it is 2001, and (2) what is covering operations at the project to date. I think that is your question.

Reply: I know there are biological opinions out there.

Bob Dach: There actually are not, well there is a biological opinion for Wells that was finished, we are working how we are covered under one law or not covered under another law, or whether it is good for fish or bad for fish. Over the last few years in our course of trying to exercise the HCPs, if you will, we have sort of been implementing them getting our feet wet, working specific measures of the HCPs over the last few years. Through that process, through the consultation process we've been trying to resolve the inconsistencies. We managed to get a major portion of those resolved for Douglas County, which enabled us to produce their biological opinion on their interim operations. So everything they are doing now is consistent with a program, whatever that may be, for recovering the species over the long-term. We're doing the exact same thing for Chelan County, but because I hate to say this, but there is only one of me, so it sort of takes me a little longer, and Chelan is a little bit more tricky because Douglas was fortunate to have a pretty decent bypass system in place so it was just a matter of making sure that all of the caveats were consistent. For Chelan we are trying to approach it in more of an adaptive way. As you work through an adaptive management process, sometimes, it gets a little complicated on how certain measures under one set of statutes relate to certain measures under another set of statutes. So, in a round about sort of way, what I'm saying is we haven't resolved all of the Chelan issues. But Chelan is in consultation with us, and every year we work out sort of an interim plan until we can figure out how to work all these other things out.

Comment: So this…for the FERC settlement agreement for Chelan.

Bob Dach: For Rock Island?

Comment: The settlement agreement for all the Mid-Columbia.

Bob Dach: There's a settlement agreement in place right now that would be for Rock Island, and yes, we are trying to be consistent with the settlement agreement, with FERC's position on enforcing the settlement agreement, with our legal authority under the ESA, with someone's desire to be protected from third-party lawsuits, with the direction that the HCP has taken us. But, so we're considering all of this in the case of Rock Island. At Rocky Reach, where there was never really a settlement agreement reached from the 1979 lawsuit, which is actually coming out. But because it was never actually reached, we're working under the Fourth Interim Stipulation and trying to make sure that that is

coordinated with everything else that we're doing. I think a good example of that is the construction of the Rocky Reach bypass, which we're working with Chelan right now to ensure that it meets the terms of the stipulation, that it meets the terms of the Endangered Species Act, and it meets the terms of the proposed HCPs.

Question: So they all should be consistent?

Bob Dach: They all need to be consistent. And you can imagine that it is easy to be inconsistent, it's a little bit more difficult to make sure that we are consistent with everything and it takes us a little bit more time. But I think we're getting there.

Comment: If I could add one thing to what I heard in that questions that was how the interim processes dovetail with the HCPs, and I think the fundamental distinction is that the HCPs are considered part of the NEPA process that pertain to the long-term operations of these projects. Whereas the things that Bob has described is the interim protection plans that are really looking at the current operations and the development and compensation of the long-term plans. So by resolving issues of consistencies, and so forth, we are not prejudging what happens in the long-term, trying to solve the problems right now. Obviously, they provide valuable information; it gets us a little further down the road toward the long-term objectives. But we were not separately, through a separate processing decision, to take it to the long-term effort.

Question: Has NMFS been trying to determine if the Section 10 is the correct section, all the time that we have been working on this, seven years?

Bob Dach: The issues that I have raised are the things that come up, you need to keep in mind that they're issues that have been generated by all of the parties. So, we could certainly say that it is consistent and I think that we have. However, it has been pointed out to us from a number of different comments, specifically through the scoping process, that we did last….. , and as a result of the 1998 declaration, people getting back with us questioning whether or not it is something that we can actually do. So those are the sorts of things that we are trying to work our way through now. Again, like a lot of these things we could very well make a decision on what we think is appropriate, but we have to be able to support and justify that with the available information. When it comes down to it, everybody in essence has to be pleased with the outcome or the process isn't going to work. Well it will work but there will be some hiccups along the way. We're working on it; we don't have it resolved yet.

Question: Bob, did I hear you say that there are parties questioning whether or not NMFS should pursue the Section 10 route?

Bob Dach: Yes.

Question: Which parties are concerned….. ?

Bob Dach: I'm not sure I remember….. Of course, council….. A couple of the environmental groups, specifically Save our Wild Salmon and…I've forgot the other one-two NGO that were not part of the original discussions.

Question: Then can I continue on with that? Then is the issue related to Trust responsibilities…..

Bob Dach: That is certainly what the Tribes are concerned with.

Question: What are the concerns of the Tribes?

Bob Dach: It is difficult to paraphrase, but in essence the relationship between Section 10 and the associated features, particularly the No Surprises, not only with the Endangered Species Act but also provisions under the Federal Power Act.

Brett Joseph: I would just caution that what is being reflected here is that in development of the HCPs there has been a consistently supported process, where we've had all of the various stakeholders, including the groups that Bob mentioned, that that resulting process going into the development of a proposal that we are not considering with the permit, but that our decision on the permit will now be on public record that we are now in the process of developing so that those groups that continue to have concerns reviewing the way that it comes together and that it will be available… in the document. That it is incumbent on them, as well as all reviewers to raise those concerns through this process on the record. What we will be relying on is this record.

Bob Dach: Is anyone on the telephone? Is the phone on?

Comment: I don't think so.

Presentation Part II

Comment: Bob, speaking of Douglas, I may have read the BO wrong, but I thought there was a benchmark catch phrase even in the BO, one that I'm concerned with that started with the EIS and that the DEIS or EIS has to be approved by the end of this month.

Bob Dach: Right. The way that the Douglas interim biological opinion is set up was that it has a definite sunset date of April of 2002. Because what we don't want is….. because the Douglas BO says that they are moving in the right direction, it doesn't say that they are doing everything that they can to recover the listed species. That is consistent with our policy, but none-the-less in April of 2002 we're prepared to go back in and say OK you guys are going to have to do all this because we need you to meet these standards for listed species. We couldn't keep pushing that off and saying every two years, "Well, they're moving in the right direction, they're moving in the right direction," because if they're not moving in the right direction quickly enough, it doesn't matter. So, that's why there's a sunset date on the interim biological opinion for Douglas. We gave this until 2002, we put that thing together a year and a half ago, or whenever it was, we made it specific to match up with how long we thought it would take us to get this agreement…the HCP, or to phrase it more correctly, to get a decision on where we're headed with the HCP.

Brett Joseph: Bob if I could clarify one point under our role under the ESA - the manner in which we say what needs to be done is through, is by means of our formulation of a biological opinion. Which is supported by the best available information through the consultation

process at that applies whether we're in a Section 10 process or Section 7, we still have to be developing the record to formulate our biological opinion. This is an iterative process that would be the framework of the biological opinion and allow us to come back to revise our recommendation regarding what needs to be done. But the distinction here is that I think comes in with context is that under the implementation agreement we do not have-we're not preserving authority to dictate what action is taken that goes with the recommendation. But I wanted to clarify that we are not making those recommendations in an arbitrary manner simply because the ultimate burden of proof is on the proponent of the action.

Malcolm McLellum: I think that was unfair. The dispute resolution process in not binding, and it indicates that it is binding and that is technically not true. It's a non-binding decision. The key is that if somebody wants to take the result of the dispute resolution forward with FERC, then the opinion that's derived from the dispute resolution can be admitted into evidence so that the hope is that by going through the dispute resolution process the parties won't find it necessary to continue to fight and be able to take that decision and act on that. And with regards to the burden of proof, NMFS specifically reserves the authority to not take an issue to the dispute resolution; they retain the authority under the Endangered Species Act to deal with enforcement issues through the ESA. That is one of the significant exceptions to an alternate dispute resolution.

Bob Dach: Let me just say that it is an issue. It can be inferred, when we look at it, not to belabor the point too much, but without being clear what it is we would be enforcing, meaning that as long as we are technically inside of the framework of the HCPs, then there would be nothing for us to enforce under Section 9 once we have issued the permit. Now what happens then is there can be some scenarios where in essence everybody would have to agree that your violating Section 9 somehow, in order for us to actually have something that we could actually enforce. Which makes the real application of this a little bit less straightforward.

Comment: As I read it enforcement of the incidental take permit shouldn't be the issue, because NMFS retains the right to enforce an incidental take permit through the ESA without first having to resort to resolving the issue under an alternate dispute resolution.

Brett Joseph: Let me just suggest that for the purpose of this hearing, this is not intended to be a debate although it's good to flag these as issues that have cropped up. To the extent that this raises questions or further clarification maybe warranted, I think it's appropriate to raise it and flag it as an issue, but what is being said here may constitute different interpretations that underscore the issue for having that issue clarified.

Bob Dach: And I have it, and I think it's good to know that it's an issue when we get to issues, I have to..… but I'm not trying to present one side over the other, so thanks for pointing that out.

Question: I have a question about the withdrawal provisions this is a 50-year HCP theoretically but in 15 years or 20 years either of the PUDs could withdraw from the HCPs unilaterally?

Bob Dach: My read is, this is an issue, so we could get into a debate. But my read is not so much that the PUDs are going to want to get out of this agreement. Correct me if I'm wrong, but my read is more that the resource agencies wanted to be able to say after the 15 years that the species weren't coming back that we want out of the agreement. It applies both ways, but in my read, I didn't see the utilities as wanting a way to get out of it.

Comment: That's correct.

Comment: This is more than an HCP under the Endangered Species Act, it's a comprehensive settlement agreement, and it's a mechanism for the parties to the agreement to say after a period of time that they can get out, if they elect to choose to. The PUDs are in a different position - this is an incentive to get as many people in the agreement as signatories and there is….. hopefully have not have trapped somebody who is in it. But if they are dissatisfied with the way it's looking after 15 years, or 20 years in the case of Douglas, that they have an option to get out.

Bob Clubb: The difference between the 15 years and the 20 years is basically because of differences in our license termination dates. Rocky Reach license terminates in the year 2006, Wells projects license terminates in the year 2012. And that was to recognize that that was a little farther out and to give us the same kind of deal that Chelan is having addressing withdrawing provisions.

Bob Clubb: Bob, could you go back to your Tributary Conservation Plan slide, I would just like to get a clarification of something. We talked about if total project survival is greater than or equal to 95 percent.

Bob Dach: Yes.

Bob Clubb: That exceeds our standard.

Bob Dach: Yeah, this actually wasn't an issue until yesterday. As I was clarifying, the differences and I knew that Douglas had a standard in there, but I was reading the standard and it seems to be inconsistent with the standards that we were talking about earlier. And indeed it is a higher standard than what we were talking about earlier, and Shane told me it was because of the expectation was that they could be a little bit higher, that they thought there was going to be a higher survival associated with the bypass.

Comment: So that if they could do better than what the standard is, the benefit for them is to be able to drop the amount that they have to put into the tributary fund.

Bob Clubb: Right. The expectation was that the Wells project was pretty friendly towards the fishery resource, and it was a recognition that the project would have that benefit.

Comment: Okay, I just wanted to make sure that's how to read it.

Bob Dach: Yeah, it's good to point out because it seems like a new standard. Whether or not we understand the definition of project survival here, is another question.

Bob Bugert: Bob, could you explain No Surprises.

Bob Dach: In essence what No Surprises says is that we can't come back five years later and say well it's not working out like we thought, or we forgot something, so you have to do this other stuff. Or you didn't address all the requirements that are necessary to address underneath the Fish and Wildlife Conservation Act, or something along those lines. When we have a deal there's some expectation on the part of the utilities that we are not going to come back for another bite of the apple.

Brett Joseph: Just to add to that. Another way of saying that we're looking across the landscape at all these factors that are maybe contributing to the decline of the species and developing our recovery plans to get species to the point of recovery that activities that are covered under a No Surprises guarantee and that are implementing the Habitat Conservation Plan that we've agreed to, will have the guarantee that as long as they are implementing that plan that we're not going to be adding on, except for a situation where we really addressed or gone to all the other activities through the other consultations, and there is kind of an escape valve where if the species is still in decline after you exhaust all remedies that you have to reassess what needs to be done across the board. But we are not going to be singling out, going kind of in the first instance to the PUDs to gain additional recovery benefits.

Bob Bugert: Can I ask a little clarification on that. Is there a precedent under the Federal Power Act for No Surprises that FERC has had to make a ruling on at all? Has this situation come up yet?

Merrill Hathaway: I think you know that the No Surprises policy was produced in the last administration and was an executive department's initiative to address concerns with the flexibility of the Endangered Species Act enacted by the administration to make it work, so to speak, and is a very important concept if the Endangered Species Act is something that the American people cannot accept…..how people would support it. And it seems to make a lot of sense but we kind of observe that from the point of view of an independent regulatory agency, but the long answer to your question. No there is no ….. , unless you're talking about the Federal Power Act about analogs, depending on how these scenarios workout there is no….. I think the Commission has strongly supported all sorts of collaborative efforts….. subtleties of legal and other questions of the Habitat Conservation Plans as being a collaborative effort, people working together. You know….. so we very much appreciate that and therefore people work collaboratively; they're trusting each other and we hope that if it doesn't come to the point where somebody says "Gotcha," you know, or if someone says, "Guess what heads, I win tail you lose." So, I think the Commission would do it's part to try take the sense if this comes before the Commission, the Commission's responsibility that we would act as consistently as the rest of the .....

Bob Dach: One more thing about No Surprises, it's applicable to all plan species so if sockeye or fall chinook were to be listed in the future, there would be no additional requirements.

Steve Hays: Bob, I think that it's important to point out that the requirements that you are talking about are the survival requirements. If you're not meeting the survival standards then additional tools or whatever would be implemented through the appropriate committee. It's a little bit different from what most people think of HCPs for…or other land use actions. In this case, the survival standards are the requirements subject to No Surprises and the actions necessary to get to those standards can vary considerably.

Brett Joseph: Maybe it would also be appropriate at this point in the presentation to make one additional point. And that is Bob's just gone through a long list of issues some of which are still sort of pending and were never resolved in the negotiations, some of which have been identified by NMFS in preparing this DEIS and others which have been identified by other parties in discussions that have occurred over this period of development, and so we're not distinguishing kind of the source of the issues other than to just flag them as areas of focus. But I also want to mention that not withstanding all of these issues, NMFS has made the decision to proceed with the NEPA process on the expectation that, and actually this is a mutual expectation of the parties that were involved in the negotiations, that not withstanding certain unresolved issues that it would be appropriate and informative to proceed with the environmental review process. And then taking in comments and views obtained through that process as information that our hope is will assist in resolving these issues. So that we can not only make a decision on the permit but also to underscore the point that Malcolm made that this is also an anadromous fish agreement and so we are really doing two decisions here. One is a permitting decision under ESA and the other is a decision of whether to proceed in concluding and negotiating a settlement.

Question: Brett I probably heard what I wanted to hear, but let me ask for clarification. There's a lot of issues here that it's hard to imagine that they could be resolved very easily and is there a way to understand to what extent NMFS will allow certain issues to be out there still hanging before a preferred alternative can actually be decided?

Bob Dach: If there is, I haven't figured it out yet.

Brett Joseph: I think our intent is to avoid having significant issues that are unresolved and still out there hanging at the time that we proceed with out preferred alternative, because for NMFS at that point that we're identifying we're saying this is the alternative that we proposed to go forward with the way the NEPA process works, we're saying subject only to consideration of new issues or additional comments that have not been received. Now we're putting out this draft EIS, flagging all these issues, many of which are unresolved or there is I think there is varying degrees they are not of equal significance. But the next iteration of this will be hopefully a final EIS, if this large number of issues still unresolved, the risk is that we end up having to extend this NEPA process or extend negotiations. And it is certainly our hope that does not occur so we're really focusing on this step in the process, the review of the draft EIS as probably the best opportunity to get as much resolution as we possibly can. And then kind of step back and see where we are, reconvene the parties, because this is a negotiation. But if we need to put something further out for public review, we would have to make that judgment call at that time.

Presentation Part III

Rod Woodin: Another question Bob. One of your issues was coordination with Fish and Wildlife Service. Will that be timed such that consultation or whatever happens has to happen under the time frame to include bull trout?

Bob Dach: Yes. I don't know, we have been talking with Fish and Wildlife Service and we have offered them some plans to do this and they're busy trying to figure out how to proceed. So not knowing exactly how we are going to move forward with bull trout, I'm not entirely sure how to answer your question. We recognize that the intent is to incorporate it and include it; ideally we would include bull trout in the biological opinion that we are going to do. And so we get covered. I'm going to work it in up here, and if I haven't answered it by the end of Section III, you can ask it again.

Question: For non-listed species, I assume that your authority is under Section 18 of the Federal Power Act…..?

Bob Dach: Yeah, what we get into in the DEIS a little bit is what we would do for unlisted species and what we would do to pursue our management authority, if you will, through the other avenues that are available at our disposal. The key one being the Federal Power Act. So Section 18, 10a, 10j of the Federal Power Act. Again, we have a lot of other, these little authorities, but none with the teeth of the Endangered Species Act and the Federal Power Act.

Question: ….. you talked about time lines….. could you talk about the interactions occurring between NMFS and/or FERC and Fish and Wildlife Service over bull trout.

Bob Dach: My last discussions with Fish and Wildlife Service..… You might be able to address this a little better Mark {Miller}, but I'll take a stab at it. Fish and Wildlife Service isn't entirely sure how they want to address bull trout. The recommendation that I offered was that we draft a joint biological opinion. So after we select our preferred alternative, when we're developing the biological opinion on that we also evaluate its effects on bull trout at the same time. So we'll have a joint biological opinion, or concurrent biological opinion, and then for issues specific to bull trout that came up during the biological opinion, we would incorporate that back or at least identify they were going to need to be addressed in the HCPs. So, for instance, the one that has me the most concerned is that the U.S. Fish and Wildlife Service is saying that we don't have enough information to do anything for 50 years. So being that the case, we would incorporate that information into our biological opinions, and working through it in my mind there is some sort of off-ramp if necessary to address the effects on bull trout. And that incorporated into the….. potentially incorporated into the HCPs.

Question: The actions under the proposed alternative with regard to bull trout are actions that would have…..

Bob Dach: ….. a negative effect.

Question: They would have a negative effect?

Bob Dach: That's correct.

Question: Has Fish and Wildlife Service made any determination or made any recommendations with regard to the HCPs under NEPA concerning bull trout?

Bob Dach: I haven't talked to them about that issue. Well they don't have to do NEPA because it's not their action, it's our action. And we could in essence use the NEPA process that we have already developed to satisfy any of that sort of requirement. The biggest issue here is their biological opinion regarding the effects of implementation of the HCPs on listed species. And if they're not going to be able to say without a doubt that, they might be able to but what they've told me is that they are not going to be able to for instance give a No Surprises guarantee for the effects on bull trout for 50 years.

Brett Joseph: And since it is a biological opinion through Section 7, theoretically we could reinitiate consultation if we found something out down the road that could negatively impact bull trout.

Bob Dach: Right. And they would reinitiate consultation with us. And there are some provisions in the HCPs that I think we can underscore to make sure how they can be used. One of the provisions is that if there is a regulatory requirement that requires a modification of the HCPs then that may, there are some steps that can be taken at that point to adjust or modify the HCPs. There are some provisions in the HCPs now that I think we can explore which we have to figure out how we can use. One of the provisions is that if there is a regulatory requirement that requires a modification to the HCPs, then that may, I mean there are some issues, so there are some steps that can be taken at that point to adjust or modify the HCPs. And it may be that it makes the HCPs no longer a viable product to move forward and be adopted.

Question: Whatever the preferred alternative that you come up with, including the HCPs, then you have to consult with the Fish and Wildlife Service?

Bob Dach: That's correct. On the issuance of the permit, but see remember that we also have to consult with them on this issuance of the permit. So ideally we would consult with NMFS and Fish and Wildlife Service at the same time.

Question: So is Fish and Wildlife Service aware and prepared for that consultation?

Bob Dach: No, and I started this conversation out by saying that's what I put on the table. That's the way that I think we can handle it most easily. Meaning that we can look at the effects specifically, one of the other options would be to make bull trout one of the permit species and prepare conservation for them. But I'm thinking that that's probably not going to happen. So, what we have to do is look at the HCPs, see what the effect is on bull trout, see if they have to be modified at all to address the potential effects on bull trout. If they do, we go back to the utilities….. and say that the ESA process has shown that we have to make these sorts of modifications in order to address the effects on bull trout but we still have a program.

Comment: To get a little more specific, in the ESA consultation for bull trout there are no guarantees for the time frame of that consultation.

Bob Dach: That's why I want to do a joint consultation, so that I have a little bit of control over how long it's going to take.

Question: How long do you think it would take, it could take five years to get a biological opinion?

Bob Dach: Not legally. Anything could happen; I mean yeah you're right we could never figure out what would happen with bull trout. We could never produce a biological opinion on the HCPs. We're still trying to produce a biological opinion on the HCPs, they're consulting with us over steelhead and the HCPs. So it's not beyond the realm of reason that it will take us longer than that schedule shows.

Brett Joseph: I think that the issue currently under interagency discussion between the Services is just a matter of how the process of consultation on bull trout should be initiated. Obviously, the biological expertise on bull trout resides with the Service, yet we are the action agency for the purposes of this consultation. So it's kind of, it's not an atypical situation where prior to the formal initiation of consultation, you would use informal consultation to develop the body of the information that would be needed for us, actually in this case Fish and Wildlife to formulate a biological opinion. NMFS is not saying we have no responsibility there, but we're saying we coordinate on a lot of consultations given our dual responsibilities under the ESA and it sure should be no different here. But it is an inefficient allocation of resources just to wait…..

Steve Hays: You would have had to have consulted with the Fish and Wildlife Service over the 2000 biological opinion for the federal system.

Bob Dach: No. It's a different deal because it's not our action, the federal system is not our action. The federal system is Bonneville Power, Corps of Engineers, and Bureau of Reclamation. So they have to deal with U.S. Fish and Wildlife independently.

Steve Hays: So did they consult independently?

Bob Dach: Well, they did but it was sort of a joint, there were two separate biological opinions done. One for anadromous species and one for bull trout at the same time.

Steve Hays: So then were they able to pull that off successfully?

Bob Dach: They were. To us that's the second best. The first best is to do one biological opinion. The second best is to do concurrent joint biological opinions. The third best is to go on about different and merry ways. I guess I'm a firm believer in that most people outside the federal government don't understand that there is a difference between the U.S. Fish and Wildlife Service and National Marine Fisheries Service. So what it ends up looking like is that the government is just running around in circles, they're arguing, they can't make a decision, all of these bad nasty government stereotypes. That's how you get this.

Steve Hays: I guess my point is that that's a far more wide reaching decision that was successfully dealt with.

Bob Dach: Yeah, I don't have a concern that we can deal with this. The problem is that under the federal biological opinion remember that's all been done under Section 7. Section 7 says that with new information, change course again. Under the HCPs, with new information we don't change course, per se. We change course but it all has to be done under the framework of the HCPs. So Section 7 is a little bit more flexible with regard to the species, at least from the standpoint of FERC, than we would have under the HCPs. So it may be a little harder to work out the subtleties. Again, what it might mean is that in five years the Fish and Wildlife Service has a bunch more information on bull trout and they request reinitiating consultation. In which case we would have to do that, and if the Service holds our feet to the fire and we're stuck in this quagmire of violating, National Marine Fisheries Service violating the Endangered Species Act with regard to bull trout on the one hand because we're in agreement with the utilities and a bunch of other parties for the long-term protection of anadromous species on the other hand. That's a situation that would be untenable for us. So we need to make sure that it's clear what's going to happen with bull trout with regard to the HCPs. I think we can work it out, talking with Fish and Wildlife Service I'm optimistic that we can work something out.

Brett Joseph: I just want to suggest a couple of things, in the interest of time. First of all, we have a small tape recorder here, so I would like to encourage everyone to speak up with comments because we're sort of hoping for a transcript or a summary of comments received. And also there are a lot of issues that end up becoming questions and I don't want to create the expectation that we are going to resolve all the issues here. Mainly our objective for today is to receive the public comments. It sounds bureaucratic, but we want to get the comments of the record to clarify if we can, but we don't want to spend a lot of time debating the issues.

Steve Hays: Just another question on something that I was a little unclear of. On a federal action, NMFS action is the incidental take permit, is that correct?

Bob Dach: Right.

Steve Hays: OK, so when you were referring in your earlier slide that you were going to Section 7 consultation over the preferred alternative, you had in your mind that that was the incidental take permit.

Brett Joseph: Right.

Bob Dach: Well…..

Steve Hays: You don't do a consultation on selecting a preferred alternative under NEPA. You do a consultation when you actually decide to issue the permit. Is that correct?

Brett Joseph: Right, that's the point where the proposal that we are receiving, in the permit application, the NEPA process is triggered by the fact that we have received an incidental take permit application from the PUDs. At the point where we decide that our proposal is to issue

that permit, we've identified this as our preferred alternative, subject to the completion of the NEPA process.

Steve Hays: I just wanted to make sure that there wasn't another consultation, that I wasn't…..

Bob Dach: No.

Steve Hays: There is no in-between consultation?

Bob Dach: Right. What made it a little clearer if we had done this a different way. Correct me if I'm wrong, but I believe that you could have submitted to us, not only your HCP but an environmental document, an environmental …as well. And then that could have sufficed for a completed Section 10 application that we would then do a biological opinion on. It would require NEPA on top of that as well, but it would be a little clearer, and you saw what we were doing our opinion on. In essence what it does is mushes them together and to answer your question, no there's not some hidden biological opinion on the issuance of the permit, which would only occur it that were the selected approach.

Bob Dach: Before everyone goes, there is a public meeting tonight, another public meeting. I want to know how we did on time, whether we lost anybody, whether there are things we should change for tonight. If anybody has any suggestions, to make me even clearer. Because you all have a background in this, so folks will come in tonight, if you guys didn't have a background could you follow me?

Answer: It was clear.

Brett Joseph: Were there any other comments?

Bob Dach: My facial read says that there are no other comments.

7:00 p.m. Meeting Attendees

Bob Dach	National Marine Fisheries Service	525 NE Oregon St Ste 500, Portland, OR 97232-2737
Bryan Nordlund	National Marine Fisheries Service	525 NE Oregon St Ste 500, Portland, OR 97232-2737
Jim Hastreiter	Federal Energy Regulatory Com.	101 SW Main St #920, Portland, OR 97204
Merrill Hathaway	Federal Energy Regulatory Com.	888 1st St NE, GC-11, Washington, DC 20426
Bob Clubb	Douglas County PUD	1151 Valley Mall Pkwy, E. Wenatchee, WA
Steve Hays	Chelan County PUD	PO Box 1231, Wenatchee, WA 98807-1231
Rod Woodin	WDFW	600 Capitol Way N. Olympia, WA
Shane Bickford	Douglas County PUD	1151 Valley Mall Pkwy, E. Wenatchee, WA
Bob Sullivan	Parametrix, Inc.	5808 Lake Wash. Blvd NE, Kirkland, WA 98033
Pam Gunther	Parametrix, Inc.	5808 Lake Wash. Blvd NE, Kirkland, WA 98033

Introduction

Bob Dach: We are tape recording the meeting tonight so we can get everyone's comments down so we know what they were. I would help us out if when you made a comment you sort of gave us your name, so we know who to respond to. And either come up to the table and we can get you on the tape recorder, or just yell really loudly. But just to let you know that we are taping for the purpose of making sure that we get comments accurately. We had mostly agency folks here today so I would sort of like to get a feel for who is here

tonight. It sort of helps me out to see who is interested in it, who we're going to be getting comments from and that sort of thing. My name is Bob Dach. I'm with the National Marine Fisheries Service. I'm the one with NMFS that is responsible for doing both the environmental review, the Endangered Species Act review of the proposed Habitat Conservation Plans. So that's who I am and what I'm here for. So maybe Merrill you can just let folks know why you're here.

Merrill Hathaway: I'm Merrill Hathaway with the Federal Energy Regulatory Commission. We license or approve the licensing of the mid-Columbia projects.

Jim Hastreiter: I'm Jim Hastreiter. I'm also with the Federal Energy Regulatory Commission. I just want to mention that we're a cooperating agency with National Marine Fisheries Service on this environmental impact statement.

Brian Nordlund: I'm Brian Nordlund with the National Marine Fisheries Service.

Shane Bickford: Shane Bickford, Douglas PUD.

Karin Whitehall: Karin Whitehall.

Arnold Asmussen: I'm Arnold Asmussen, and I'm here because I have a high distrust of National Marine Fisheries Service, and I question their agenda, and I question their science, and I question the way they run this country like a dictatorship without votes on the things that control our lives from one end to the other. I would like to hear some form of reality in this meeting, and that's why I'm here, I kind of doubt it.

Bob Dach: Well, I'll give you what I know of the issues and leave it to the decision on your own on that one. But I'll try to answer questions you have.

Arnold Asmussen: In general National Marine Fishery agents claim to just be following orders, but collectively they're ruining our country. And I'm not a radical; I'm a typical farmer, rancher, and businessman. So that's what you're trying to explain to, if you'd be a little careful and try to explain the things that don't make much sense.

Bob Dach: Point them out and…..

Arnold Asmussen: I'll do my best.

Bob Dach: I don't want to defend this too much but point them out when I come across something.

Frasier Strutzel: I'm Frasier Strutzel. I represent the Monitor Community Council, and I've also spent the better part of five years or six years on the Wenatchee River Watershed Study. And my view is in line with the bumper sticker on my car out there that says "Save a salmon, plug a bureaucrat."

Bob Dach: Man, I'm going to have a hard time with this crowd.

Comment: Well, I kind of agree with what these guys are saying. I'm just a concerned citizen. I've grown up and lived on this side of the state for sixty years and I grew up on Whidbey Island and I'm a sportsman, fisherman all those years, and I've seen the incompetence of the National Marine Fisheries since they've came to being and the fishing has continually gone downhill and poor management that has continued to go disastrous up in Alaska also, other than Canada that has an aggressive plan to fix the situation. I don't think you guys are doing a very good job.

Comment: I'm like this fellow, I came down here as an interested party. About two years ago, we were down in Railroad Springs, California, and this big vineyard down there, hundreds of acres, all dead, no water. I was talking to the residents that live down there and they just ran out of water and they just died. The race track grass is all gone, the vineyards are gone, so that's why I'm interested. I don't like to see these fellows who talk about taking our dam out. We need that water.

Rod Woodin: I'm Rod Woodin with the State of Washington Fish and Wildlife. I'm here to track your public review process.

Steve Hays: I'm Steve Hays with Chelan County PUD one of the original negotiators of the Habitat Conservation Plan for Rocky Reach and Rock Island. It's our application to National Marine Fisheries Service that the proposed plan for tonight is to review the draft environmental impact statement, and Bob will be explaining the differences between our application and some of the other processes.

Bob Clubb: I'm Bob Clubb, Douglas County PUD, and I was one of negotiators for the HCP. And we represent Wells Project which is the top end of the system. The last dam that passes anadromous fish.

George Krakowka: I'm George Krakowka, concerned citizen. Do we get a chance to talk later?

Bob Dach: Sure.

George Krakowka: OK. That's all I'm going to say now.

Dave Poirier: My name is Dave Poirier representing Lockwood Canaday Irrigation Company.

Whitey Excubus: I'm Wade Excubus, mayor of the city of Rock Island.

Tom Clark: I'm Tom Clark. I'm a public advocate and promoter of salmon recovery.

Steve Lachowicz: I'm Steve Lachowicz. I'm with Chelan County PUD Relicensing Team, a project that will be impacted by decisions that are made on the Habitat Conservation Plan.

Lonnie DeCamp: I'm Lonnie DeCamp. I live in Chelan County.

Lonnie Murphy: I'm Lonnie Murphy and at present I work for Chelan County PUD. Part of the year I also work for the Forest Service in this area and I'm here tonight basically at my own

personal will because I'm interested in what your findings are and seeing if they correlate with what happens.

Svend Westlund: I'm Svend Westlund. Just a curious Douglas County resident.

Elisabeth Westlund: Elisabeth Westlund, I just want to learn more about what's going on.

Pam Gunter: I'm Pam Gunter with Parametrix and we're helping to do the NEPA process and I was hoping that anyone who hasn't signed in can do so.

Bob Sullivan: I'm Bob Sullivan, also with Parametrix.

Bob Dach: Thanks, like I said, I like to know who my audience is.

Presentation Part I

Arnold Asmussen: Why don't you have a part in there [comprehensive strategy for dealing with ESA listed fish species] about working with the public, do you have no desire to do that?

Bob Dach: We do.

Arnold Asmussen: It wasn't listed on the slide.

Bob Dach: I probably should have. For instance, this forum, the whole NEPA process, and I'll get into it a little bit further in the presentation. But the whole reason behind it is such that we can get all the information that we don't have down on paper, and get it out to everybody, the general public, agency decision makers, anybody that's interested. And get their feedback and comment. And we actually have a couple of very specific steps in the process to insure that we are soliciting public comment. Then we go through a process by addressing those comments.

Arnold Asmussen: OK, excuse me I guess I misunderstood. I just thought that if your reason for existence is to serve the public you would list it.

Bob Dach: OK.

Arnold Asmussen: I have a question and I don't want you to think I'm here just to agitate you. I really have an interest in this whole process.

Bob Dach: That's OK.

Arnold Asmussen: Looking at Section 10, does that cover private parties, such as people wanting to drive their boats or have things to do on the Wells Pool?

Bob Dach: Right. If your action is prohibited under the Endangered Species Act, if it's actually going to result in the take of the species.

Arnold Asmussen: That's a pretty broad thing, does this take include to harass?

Bob Dach: Yeah, it could be.

Arnold Asmussen: ….. to look at, and are boats going to be included in that do you know? Or who makes that decision?

Bob Dach: I don't know how to answer that question specifically, you know.

Arnold Asmussen: Because it's really broad. There is business interests I'm sure up and down the river that would like an answer to that.

Bob Dach: Right.

Arnold Asmussen: And I don't think that the boats bother them that much.

Bob Dach: Whether or not specific actions need to have an incidental take permit, I don't know. I don't know, as you say, the definition of take is pretty broad.

Arnold Asmussen: So you're developing federal law to the conditions?

Bob Dach: Well, we're not really developing federal law in this case. What we're doing is evaluating the action of permitting the take that results simply from operating the power plants. So we're not looking at …..

Arnold Asmussen: So, you're just looking at the power plants tonight, in this session? It's confusing.

Bob Dach: Yeah. No. The action that is in essence on the table to us is the action of continuing to operate the power plants.

Arnold Asmussen: And the power plants somewhat license the pool behind them, and control what activities take place on each pool?

Bob Dach: I don't know that, in either case, we're not looking at indirect activities that are related, for instance, to recreation on the pools. We're looking specifically at operation of the projects themselves and the effect that operations of the projects have on these fish. So we're not looking at boating, or fishing or anything like that on the pools themselves. Only, in essence, the fact that the dams are there and generating power, and that will go on.

Arnold Asmussen: I'll reserve those specific questions until I…..

Bob Dach: And then again, I got into it a little earlier; this is a coordinating proceeding.

Presentation Part II

Bob Dach: ….. the allocation of unavoidable mortality is not transferable. Why that's in there is specifically to show that if, say you're only getting 89% total project survival, you wouldn't make up the difference by increasing the number of hatchery fish you put in the water.

Arnold Asmussen: Why?

Bob Dach: The hatchery fish themselves don't lead back to the….. in essence the original listing issue. Which the example I used was the 359 redds on the Wenatchee.

Arnold Asmussen: I'm sorry, I'm a little dense on this one. First of all, I have a question. As I drive to Portland about five times a year, I see hundreds of nets. How are you going to get the fish past the nets to the dams….

Bob Dach: The way I can answer it is that they go through a similar process to determine how many fish they can actually keep. So we have a take that is associated with activity then there is a certain level of take that is allowed. They get to…..

Arnold Asmussen: Who decides it?

Bob Dach: National Marine Fisheries Service.

Arnold Asmussen: That's important, that's why I'm here. You guys are not doing a good job. When they first, when the nets, when they first gave the treaties the Indians caught their fish with nets and spearing. Now if they do that again, they can have all the fish they want.

Question: Do you know the current success rate? I think Wells Dam is one of the safer dams on the river for fish. Do you know what percent of juveniles currently pass through Wells to survive the nitrogen loads?

Bob Dach: The survival level that we have for Wells from evaluations that they have been doing for the last three years show, I want to say for juveniles and this includes the pool, Shane can address this as well because he is the one that is actually conducting the studies. But we're looking at right about 95 percent pool and dam passage survival. The adults, we haven't really, this will come up later, but we haven't figured out how to measure survival in adults yet.

Arnold Asmussen: But they might be doing a little better because..…

Bob Dach: The thought process is that adults are doing better. Yeah. We just don't know how to measure it. But we have measured juvenile dam and pool for a couple of species, juvenile steelhead and yearling chinook. And they're coming out right about 95 percent.

Bob Clubb: Actually the average for the three years is a little better than 96 percent.

Arnold Asmussen: So the best dam on the river is just right on the border of that number.

Bob Dach: This number here, juvenile dam passage survival, is a little bit different than pool and dam passage survival and that's what the Wells studies represent. This 95 percent is just, in essence, through the forebay, dam, and tailrace. The information that we have generated at Wells also includes a significant component in the Wells pool. So the thought process was that between the Wells pool and the Wells dam that survival would

be, it had to be about 93 percent and they're getting 96 percent so they're beating it by about 3 percent. At least for those fish that were tested.

Arnold Asmussen: So you're saying that if you can get 91 percent survival of the smolts heading down the river, you talked about getting them back to recover the species, or are you just talking about getting them out to the ocean?

Bob Dach: The 91 percent number is the number that includes the mortality associated for all of the smolts going out and the adults coming back up. So the combination of all the associated mortality has to be less than 91 percent, less than 90 percent.

Arnold Asmussen: Well then, I want to call your attention…..

Rod Woodin: Just that one dam.

Arnold Asmussen: Just for one dam?

Bob Dach: For one dam, right.

Question: What should be done about the island down there with all those gulls that are…..?

Arnold Asmussen: I was just going to bring that up. Rice Island, are you familiar with that? Forty miles from the mouth, there's 8,000 pairs of nesting Caspian terns down there and they eat between 10 and 20 percent of the salmon migrating past the island. That is not a guess; that is tracking salmon with rice grain sized tags. Thousands of these tiny tags end up consumed, digested, and deposited on the sand of the island. Ten to 20 percent of our salmon we're losing down there, yet nothing's been done about it by the National Marine Fisheries Service and I was just wondering if you just don't care about those 10 to 20 percent,

Bob Dach: Well…..

Arnold Asmussen: Only here at the dams.

Bryan Nordlund: I could actually talk to that a little bit because I work directly with the biologists that worked on that project. There was an attempt that was successful to modify the habitat so that the terns don't nest as readily on Rice Island. That was done in recent years. I guess maybe not so surprisingly there were some groups that were offended by that action. They felt that impacts on arctic terns were not any more tolerable than impacts…..

Arnold Asmussen: So those groups were adhered to, and the terns are still there eating 10 to 20 percent of the salmon?

Bryan Nordlund: They actually, what has happened is the terns a lot of them have relocated off of Rice Island now. They're not in as big of colonies as they used to be.

Arnold Asmussen: I mean those groups overrode the idea of shooting the birds to protect the salmon.

Bryan Nordlund: They had some additional modification planned and there was a court injunction that stopped us from doing any additional habitat modifications because of impacts on migratory birds.

Question: What's the percentage that we're losing there?

Arnold Asmussen: Ten to 20 percent.

Comment: I had a follow up to my question. You said that you decide, U.S. Fish and Wildlife, whatever, National Marine Fisheries Service, decides how many fish they can take out of the river with their nets.

Bob Dach: We have a, we have the, we decide, yeah, we decide. It's not quite that simple. As you can imagine there are a number of interested parties that all have a position, that all gets weighed in any decision that's made. We'll make the final call of that take permit issue. So that we don't do it in a box, so I don't want to imply that. We might not make the right decision, but we at least get a lot of input.

Bryan Nordlund: Keep in mind too…..

Comment: You make that decision each year? When you talk about this, they've been in the river for years now and we even ….. less and fewer and fewer salmon.

Bob Dach: We evaluate the decision annually. So the decisions are…..

Question: So, have you ever published how many fish you allow them to catch?

Bob Dach: Yeah. The percentage of fish allotted to, and again it's the percentage of fish allotted to the Tribes, as it relates to our concern that indirectly they would be taking a lot of wild fish that should be up on the Wenatchee spawning. So they can catch a lot of fish, but their component of the population that's the wild population is really the one that we're concerned with.

Bryan Nordlund: Also you have to keep in mind that Bob and myself are, we're particular to the hydro portion of NMFS, there's other divisions that do sustainable fisheries, is the action you're talking about now. And the Rice Island issue was a habitat issue that our habitat division is handling. We can talk to it but that's not really what we're here for tonight. I mean we're, I mean I would be glad to…..

Arnold Asmussen: I have one more thing I would like to cover and that is I think the reason we're all here is because somebody in the National Marine Fisheries Service had determined that there is a difference between wild salmon and hatchery salmon when DNA testing has shown there is hardly any, if any. But to have a person working out of your office in Seattle, Robin Waples, a senior scientist of National Marine Fisheries Service said he is in favor of getting more data for DNA, but doubts his agency's conclusions will change. In other words, he is going to ignore science, he's a scientist hired by the government and tax payer dollars to evaluate science and implement it, but he's saying he's going to ignore it ….

Steve Hays: Bob, I would just like to mention that, I don't remember the date, but a local group is having Dr. Waples and a ….. geneticist speak here in Wenatchee, as well as a neutral geneticist as well.

Bob Clubb: March 20th.

Steve Hays: March 20th, so you'll have a chance to ask that question…

Bob Clubb: It's at the Red Lion, I think at 7 o'clock.

Shane Bickford: There is also a meeting in the Methow on the 21st, the same group.

Arnold Asmussen: To finish my point, sometime in the last million years two chinook salmon swam up the Columbia River and now we have some biologists who have determined that that is now over 300 separate distinct species that are the offspring of these salmon.

Bob Dach: Stocks.

Arnold Asmussen: Do you know how many total stocks they've determined.

Bob Dach: No, I don't know how many separate stocks there are.

Arnold Asmussen: But I, if we, if these people keep going on they'll take every little creek off the side of the Wenatchee River and they'll have a spring, summer and distinct species for the spring run, summer run, and fall run for each little tributary whether it has any water in it or not. I mean, these people are creating species like some people pass gas. If it weren't for these people being able to declare that these salmon are genetically different, which the DNA doesn't support, we wouldn't be here. The hatcheries would be putting out the salmon that we need. And one more point I'd like to make, here's a top Canadian fisheries biologist named David Welch, and he….. this ….. ocean theory, by telling about the pristine, undammed, Keogh River in British Columbia. Where the coho run has dropped 90 percent. There are no dams on this river but the coho run is down 90 percent since 1970.

Comment: The same goes for the Olympic Peninsula, there's no dams on it, the same goes for Alaska. There are no dams on those pristine rivers at all.

Arnold Asmussen: We're here over some fantasy that some biologist has that we've got these different genetic, and they all started with two salmon hatching. That's why we're here.

Comment: Did you ever hear the word overharvesting….. They're the ones that control that.

Bob Dach: I'm not a good person to debate it with you. There are folks that know way more about it than I do. It would be great if they were here.

Arnold Asmussen: I'm afraid they don't work for the National Marine Fisheries Service. We wouldn't have this problem.

Bob Dach: I could just give you my opinion, I couldn't quote facts and data on it.

Steve Hays: Just a real quick note so we can put things into perspective here. National Marine Fisheries Service obviously has management responsibilities to manage the fishery, manage the habitat, and manage other stuff. But Bob's responsibility is to manage the hydro system actions through the FERC. He didn't write the law, of course there are congressmen out there to review the law. That's one point that you might take up. The other thing is that not even National Marine Fisheries Service is immune to lawsuits and the Rice Island incident they wished to be more aggressive to relocation that the Audubon Society and others allowed them to, and were prohibited by a court injunction. They also have proposed an initiative on a lower percent harvest on some of the fisheries and were successfully sued by an advocacy group. So I guess the whole mess is what comes around, goes around, comes around, so just keep that in mind too. Today though we are talking about the two local PUD's proposals to the National Marine Fisheries Service for a plan to maintain long-term operation and to relicense our hydro projects through a Section 10 process for which we could use more local input. And Bob's going to explain the difference between that and a Section 7 process, which is the federal to federal negotiations that occur for the federal projects which is another alternative that could be used in place of ours.

Comment: I just had one more comment. I know that we've kind of gotten out of focus on the hydro projects impacts, but I think everyone here probably realizes that they do have their…salmon passage and survival. I was wondering if you could clarify the 9 percent unavoidable mortality because that actually is more like potential mortality? I guess you're requiring them to meet 95 percent but yet allowing 9 percent?

Bob Dach: No. We're actually requiring that they meet this 91 percent, that's for a combination of juveniles and adults. So this 9 percent mitigates for that. The 95 percent is a sub-product of this, meaning that 95 percent, specifically of the juvenile population, and specifically at the concrete. So you could look at total juveniles need to be 93 percent, which allows 2 percent mortality per dam on adults, if you wanted to. There is some intent behind those numbers, but the number of importance is the 91 percent, and the 9 percent that we're mitigating for, but it's a combination of juveniles and adults.

Rod Woodin: Bob, you might also clarify that if the measures at the projects achieve greater than 91 percent survival, and it's documented, that the 7 percent hatchery production won't be reduced.

Bob Dach: Right.

Steve Hays: The reason that there is a separate number for at the concrete is because there's a lot more opportunities to do things to improve salmon survival at the dam than there is out in the reservoir, for example, where you have less ability to change things. So that's why they're separate numbers. There was a certain amount of effort that was negotiated as to what we would do at our dam in terms of operations and structures to prevent loss of fish, primarily through turbine passage. That, theoretically, you could only get so much

benefit through anything you might try in the reservoirs so it's an additional allowance for reservoirs and adults…

Comment: I have a question, Bob. This agreement, those numbers, apply specifically to each dam, Wells, Rocky Reach, so you're going to have 9 percent unavoidable mortality at each dam?

Bob Dach: Correct. Times nine if they have to go through nine dams.

Comment: Bob, I would just like to make sure people understand the point about the kind of money that each utility is paying for the habitat improvements over the 50-year life of the proposed plan. Do you have totals for each of the utilities and what that will amount to over 50 years?

Bob Dach: I do not.

Bob Clubb: About $42 million.

Bob Dach: Do you know for Chelan?

Steve Hays: That's for both combined.

Bob Dach: Oh, that's combined?

Comment: $42 million - that could buy a hell of a lot of fish downtown, couldn't it?

Comment: Buy a lot of commercial fishing boats too.

Arnold Asmussen: It could take the whole National Marine Fisheries Service out to dinner.

Bob Dach: Just pay us off and go home.

Comment: Then you'd have to find a job.

Comment: Withdrawing from the plan in 15 years for Chelan and 20 for Douglas. Is it going to be a process established for those two PUDs to approach the agencies to exit the plan?

Bob Dach: There is a process. Basically what it comes down to is that after 15 years, for example for Chelan, if after 15 years the species is continuing to decline then we, the resource agencies, have the option to opt out. There are some caveats in that, so there are some requirements that must be met. But the idea was, that to the best of our ability, we picked the wrong standards and the species are continuing to decline, or we have the right standards and they're still continuing to decline because the measures weren't appropriate, or something. We would have the option to back out of this process and then decide if something different needed to happen. The reality of the situation is that due to the flexibility that the proposal has in it, ideally if we weren't meeting the standards in 15 years, or the species were continuing to decline, there would be ample room inside of the framework to allow us to regroup mid-stream without having to back out of the

agreements. But again, it's in there as a last ditch effort because nobody, as you can appreciate in the federal government, likes to think that they can't make a decision for 50 years. So this is just in case.

Comment: Bob, another comment on the amount of money that Chelan and Douglas PUDs are agreeing to pay over 50 years, is it?

Bob Dach: Over the term of the permit.

Comment: $46 million?

Bob Dach: Taken on good authority.

Comment: Chelan County PUD right now has allocated $44 million for diesel generators that are being installed at Alcoa. The projection is for that $44 million to be paid off in 5 months.

Bob Clubb: I would just like to say one thing, it was actually $42 million for the Tributary Plan, which is just one component of the Habitat Conservation Plan. I addition to that, we produce 7 percent through the hatcheries. Douglas spends $2 million a year on hatchery O&Ms, plus the initial capital contribution. And then there are things being done at the dams that cost millions and millions of dollars. Chelan PUD is proposing to have a surface bypass system, and it is going to cost $168 million. So it's not a fair thing to speak of, that we are just paying $42 million dollars over 50 years for the protection of the resource. You have to have all of these many items that we're doing, which are hundreds and hundreds of million of dollars over the course of this 50 years, not 42.

Bob Dach: I tend to just add to that, when you start talking about money you always get into those sorts of comparisons. The money, the dollar amount was certainly at the time considered to be adequate to cover that mitigation component. So it wasn't as though the utilities were trying to get away with as little as possible. It was that this is about the kind of money that was going to be required in order to do these improvements as a result of the tributary program. We could have asked for more money, but as we work our way through processes we like to be sure that whatever we're asking for, whatever we're going for, whatever our bottom line is, is pretty well seated in the available biological information. People will disagree with the available biological information, and that is one of the reasons that we do these public processes and take comments and do all that other stuff. We put the information we have on the table and people take shots at it. The stuff that we have, I think tends to support the dollar amounts. And again, conscious about the dollar amount itself, just in that, we want to make sure that we have an adequate programming. And I think the take-home point is that the utilities are prepared to ensure that they're funding adequately to take care of that component of the program. Is that reasonable?

Arnold Asmussen: Bob, you're saying that if the stock has continued to decline, or are you taking other factors such as weather, or drought, or anything like that into consideration? Or will it be strictly based on the dams.

Bob Dach: It's quite an involved process, and I don't even understand the ins and outs of the process, but what it does is, it looks at returns, if you will. It looks at the total life history of populations over the course of, I think from our prospective, you really need to look at over a course of about 15 years in order to get a reasonable, in essence, data point. Then you look at whether or not the line from today to 15 years, is moving in this direction or it's moving in this direction.

Arnold Asmussen: I grew up on the Wenatchee River. I've lived …. I've grown up on the river and I know we were in an extreme drought, except from three years, from 1969 clear up to the middle 80's and I know that it had a very bad impact on salmon ..… In '87 U.S. Congress directed the U.S. Army Corps of Engineers to investigate causes of declining salmon runs. And this was 1887. You know, these things happen regardless of the dams. I wonder if you take in the weather conditions.

Bob Dach: Yeah. We're not, because this particular component of the puzzle being discussed here tonight, try not to misconstrue that as being the only thing that is being done, the phase of the recovery, to recover fish populations. It's really not the case. There are things being done everywhere.

Arnold Asmussen: I was nervous about it just being pinned on the dams themselves.

Bob Dach: Yeah, it comes across that way, the dams are big visible objects and we do a lot of big visible expensive work at dams. But I think that if you ask anyone they know that, if you ask somebody that is trying to irrigate crops out in the Methow, for instance. They know that they're not getting away with anything. And the tribes will tell you, if you sit, if I were to go to a tribal meeting, the tribes will tell you it used to be we used go get, we used to have fish coming out of our ears. So, it's a very broad based multi-facetted issue.

Arnold Asmussen: But in 1887, without a dam on the river, congress took it upon themselves because of the severity of the situation, to direct the Corps of Engineers to..…

Bob Dach: Yeah, I think that weren't the conclusions of their report were….. I think they came to overfishing. They said all the big fish wheels down the lower Columbia had to go. From what I remember of the report.

Question: I'd like to say ….. are there any documents put out by National Marine Fisheries Service that address all of these issues affecting salmon, so these people might get an overview?

Bob Dach: Yeah, there's a few. We have a thing we now call the all H paper. All of these are on our website, and our website is in that handout information I gave you. But there is a lot of information on species status reports, there's what we call the all H paper, which addresses, we used to call it the 4-H paper but I think somebody had a copyright on the 4-H's so we had to change it. It's hatcheries, habitat, harvest, and hydropower. So those were, in essence, the big four that we evaluated under this, what we call the all-H paper.

Arnold Asmussen: But weather is not included in those?

Bob Dach: Pardon me?

Arnold Asmussen: But weather is not included in those?

Bob Dach: Well weather comes into play.

Arnold Asmussen: In habitat?

Bob Dach: Yeah, weather comes into play in all of the analyses that you do. This is one of the reasons we say that you can't get one year of data and call that the answer. Because it doesn't take into consideration environmental variables, weather. So that's why you have such a long period of time before you know, that's why you have 12 or 15 years or 15 or 20 years before you know whether you've done good or bad. Because it takes a while to generate that kind of information. But you can't, as you know, say well this is the data point that we got this year but it was a dry year, so we're going to add a fudge factor of 14 percent. It just doesn't work that way.

Steve Hays: Your ocean factors are worked into the CRI.

Bryan Nordlund: CRI and QAR both.

Bob Dach: The CRI is actually now three papers, from what I remember. One of those has been published and two of them are on the way; they're on the website as well. And we have the cumulative, cumulative analytical report, quantitative that's it.

Steve Hays: So that's it?

Shane Bickford: QAR, CRI is the cumulative risk initiative.

Bob Dach: Thank you. But there is probably a hundred other models that other people have done as well. The one's that we have, that we rely upon, are on our website and have been published. And the last big analysis that we did, I think the best analysis that we have done so far, was the one just released in the federal biological opinion on the operation of the federal hydropower system. So BPA, Corps of Engineers, and Bureau of Reclamation, and I think there was 43 dams in that one, something along those lines. And they looked at everything. Bonneville Power out there is trying to fix habitat because they think that they are going to get more of a survival improvement in habitat than they are if they keep tinkering with the projects.

Steve Hays: The bottom line in that decision was the decision not to remove the Snake River dams because other indications were that there might be more loses occurring elsewhere. Is that correct?

Bob Dach: Well the bottom line was removing Snake River dams, in and of themselves, was not a guarantee that they were going to recover fish species. So the politics behind that, then why in the heck would you do it. So where NMFS was at was we don't necessarily know that we can save fish species without removing dams, but we'll work on it for a few years, we'll see if there's a way to keep the dams in place with a bunch of experimenting if there's any way we can recover these species leaving the dams in place. That, in essence, was the decision.

Bryan Nordlund: The other component of that too was you pick out four Snake River dams and it doesn't put any more fish in the Wenatchee River, for example. So that it's broader than just those dams. In looking at all these other habitat, harvest, and hatcheries used in addition to hydro it gives us a chance to try to put in a more comprehensive program together that will address recovery in all the different areas, not just in one particular area, which removing the dams would do.

Comment: When you talk about the species status in 20 years, are you talking about wild species or hatchery species?

Bob Dach: Under the Endangered Species Act, it would be naturally producing species of wild fish, not hatchery fish. Well, not hatchery fish per se. Some of the hatchery fish are covered as well. But we're looking at wild populations. Which is an issue because, you know, when you're talking, probably this year we'll have one of the biggest spring chinook runs we've ever had. It's just not associated with a big wild spring chinook run, unfortunately.

Frasier Strutzel: Excuse me. Bull trout use to be called Dolly Varden until

Bob Dach: Hey, that's Fish and Wildlife Service.

Frazier Strutzel: Until the biologists got hold of it. But we used to have a big run of silvers, silvers we called them, on Lake Wenatchee. Since the protection of bull trout has come into being now the Lake Wenatchee coho aren't there anymore. Isn't Article 3 of the Endangered Species Act concerned with controlling predators.

Bob Dach: I'd have to read Article 3, I don't know off the top of my head.

Frasier Strutzel: I think that either Article 3 or Article 4 says you look to control predation.

Bob Dach: It seems reasonable that's in there somewhere.

Frazier Strutzel: And bull trout is the worst predator in the world on immature salmon, that are an endangered species.

Bob Dach: So what do you do?

Frasier Strutzel: So why are we protecting them?

Bob Dach: So what do you do when one listed species is preying on another listed species?

Frasier Strutzel: Well, you shoot one of them, then you have the other.

Bob Dach: Save the one you like better, huh? Well that's what we worked, that's what we consult with U.S. Fish and Wildlife Service over. Because we have all these plans…..

Frazier Strutzel: It's contradictory.

Bob Dach: Yeah. We have these plans for, you know, the federal government believe it or not is not one big happy family either. The U.S. Fish and Wildlife Service has their species of

concern, we have our species of concern. When we get into this sort of deal, we sit down with those guys and hash it back and forth about what we're going to do for endangered fish.

Frazier Strutzel: So you duke it out?

Bob Dach: Yeah, that might be easier.

Karin Whitehall: I have a comment. If you think back a hundred years ago, 200 years ago, bull trout and salmon co-existed here, so to say that they are a voracious predator on salmon doesn't really make sense. They co-existed.

Arnold Asmussen: The silver runs in Lake Wenatchee are eliminated, and nobody's concerned about that. They are gone. You can't find any silvers in Lake Wenatchee, they've been eliminated.

Bob Dach: Well, you know, this is a, the issue I think that I hear you bringing up, is one of the reasons why Habitat Conservation Plans are appealing. Because it looks at all of the interrelated issues, it doesn't, it intentionally doesn't select one fish over another fish. It provides the program necessary in order to allow these fish to cohabitate. But I understand what you're saying.

Arnold Asmussen: Yeah, they're eliminated so that entire species is gone. You just can't find in Lake Wenatchee. We used to catch them, 20 or 30 at a time when I was a youth.

Shane Bickford: Isn't that part of the 9 percent? (Bob Dach said: The combination of effects [of all three dams] leads to an additional mortality that you won't see in the project area. These HCPs don't really address that. They do to a degree, it's just not completely clear how it's addressed.)

Bob Dach: No. The 9 percent is for fish that are moving through your project. Not the fish, not what happens to them when they get down to the estuary.

Shane Bickford: Unavoidable mortality doesn't take that into account?

Bob Dach: No.

Malcolm McLellum: But Bob, didn't you say before that it's 9 percent allowable take?

Bob Dach: Per dam, so nine times nine

Malcolm McLellum: Nine dams. So that's 81 percent loss.

Bob Dach: It doesn't really work like that, but…..

Malcolm McLellum: No it's not, I didn't finish, I wasn't allowed to finish. It's 81 percent if a 7 percent hatchery program is not working.

Bob Dach: It's even if the hatchery program was working, it still would be a significant component of the wild fish that was not..… So each one of these dams takes a piece, but the issue is a fish that survives through all three projects up here. Survives through the Wells project, the Rocky Reach project, and the Rock Island project. A component of those fish that survive through these projects may die later because of the trip through the system. In which case, there would be a burden on each one of the utilities for that cumulative effect on the species. Everybody takes a scale, fish can only lose so many scales before it dies. So there's…..

Malcolm McLellum: But that's a part of another program that says that the net cumulative effects are not addressed.

Bob Dach: Well we're trying, they're not addressed under the HCPs. So we're, it's an issue that's been identified.

Question: One of the objectives of the Endangered Species Act is to recovery species and to delist them. Right?

Bob Dach: Right.

Question: So what would happen in the event that you saw a delisting of affected species before the 50-year tenure of the agreement was up?

Bob Dach: That's a good question. I don't know what would happen.

Question: There wouldn't be any need for the HCPs?

Arnold Asmussen: You would have to create a new species and declare it endangered.

Bob Dach: Yeah, something would have to get endangered.

Bob Clubb: Well it's more than just endangered species.

Steve Hays: Yeah, the PUDs are proposing to amend their FERC licenses with these plans, so even in the event that these species were delisted and there would be no longer a need for a Section 10 permit. But all the actions taken to preserve and protect those species would have become part of the FERC license, that would remain in effect until the licenses were amended, or until the license term ended and another federal license was issued. So that, the answer to your question is, if these are approved and become part of the license, then it becomes part of FERC's responsibility to make sure that it continues to be implemented, even though the need for a Section 10 permit will go away, if the species were actually delisted.

Bob Clubb: And I think the original intent of the HCP was to provide measures that prevented the necessity for the occurrence of listings.

Bob Dach: Yeah. It wouldn't behoove anybody to just all of a sudden say OK we're done. So, although I wouldn't want to commit the utilities in, like I said it wouldn't seem prudent to

stop doing anything that they had been doing that's resulted in recovering the species. It would be, we would drink a beer over it, I'm sure.

Comment: I'll buy it for you.

Steve Hays: I expect to be pushing up daisies before they're delisted.

Bryan Nordlund: It would take all the fun out of public meetings too, if we're not doing anything right and the species were actually recovering.

End of Presentation

Bob Dach: I can answer any questions, or I can try to…..

Arnold Asmussen: Yes, I have a question.

Bob Dach: Make it something that I didn't address.

Arnold Asmussen: Well, I'd like to give my name and have a written response from NMFS on this one.

Pam Gunther: Well, you know, at this point I would appreciate it if you could come to the microphone so that we can be sure that we have exactly what you say, and state your name first. It's to your advantage.

Arnold Asmussen: My name is Arnold Asmussen, and do you need the address?

Pam Gunther: No, I have it.

Arnold Asmussen: I'd like to make an observation. Back in 1997 when this started, and I'll be a brief as I can, I sat in a meeting up in, I believe it was Twisp, and I asked why a federal agency, such as NMFS that had federal authority, and in my opinion and that of others should be protecting citizens rights from the outside interests, outside of the United States. In the context of federal authority, therefore federal responsibility, I questioned the Indian fishing which consider themselves, depending on what day it is, consider themselves an independent nation and the offshore fishing, outside of our waters, or in our waters by other nations. And those things seem to be the last things that have been addressed, or effectively addressed. And the first thing that our federal agency did was to start taking away private citizens' water rights and property rights. Which is the easiest thing and took the least amount of will and resolve of the National Marine Fisheries Service to do. But it was the first thing that they effectively did, was to take things away from our citizens, while they allowed citizens of other nations to go ahead. Now they lodged protests and they did things to try to curtail it, but effectively no. The Okanogan has a tributary 2 percent of the problem and the terns, I think it's been well documented 10 to 20 percent, perhaps less now are an unprotected species. Is that correct?

Bryan Nordlund: They're protected by the migratory birds or…..

Arnold Asmussen: Well, all animals should be protected. I'm not an anti-naturalist, I believe I want our area to stay nice. But those terns are not an endangered species. And I don't believe they're threatened. They're living on an unnatural island and a small group, I don't know how small….. perhaps large on the internet, got together and decided to protect those birds that are taking 10 to 20 percent of the fish. Now, it has to sting a little bit for the National Marine Fisheries to say well we have to turn back because of that environmental group and not take care of that 10 or 20 percent issue, but we are going to go ahead, and there is a little group up in the Okanogan of citizens, farmers, ranchers, county commissioners, and even recently the Okanogan PUD voted to support the law suit against National Marine Fisheries with $20,000. And that is being ignored. They're going to go ahead and take care of that 2 percent but they're ignoring the 10 to 20 percent of these birds that some environmental group decided to protect. I see that as completely wrong. It should be illegal. And my question is: Why are those terns getting more consideration than the Okanogan and the farmers and ranchers up there? When that's 2 percent and this is 10 to 20 percent. I'd like a written answer. Thank you.

Comment: I just want to say a little bit….. some of you here might not be aware of, but maybe a lot of you are. In the north Atlantic, they had huge numbers of fish for years, no dams, now there's practically no fish. They finally realized it was overfishing and they're trying to do something about it. The Frasier River never had a dam, huge numbers of salmon going up the Salmon River. I was up there, I came here 50 years ago, and I was up there and watched those salmon go up the Frasier River. Now there's none. No dams, no fish. Then south of China, in the islands south of China, there used to be a lot of fish and they finally admit there is too much fishing, there's practically no fish left from overfishing. Not Americans, by the way. And I think that we ought to extend our boundary line. It's only three miles out now, from what I gather. Does anybody agree with that? That our national boundary in the ocean is about three miles out.

Bob Dach: There is an economic exclusion zone, I think it's, I want to say it's 49 miles out.

Question: It is?

Bob Dach: But you could be right, I'm certainly not sure.

Comment: Well, I heard that Japan has 150 coming this way. I don't know if that's true or not, but you hear things like that. And, what is the problem then? It's overfishing, overfishing. Foreigners come in to our area; we're breeding salmon for them to catch. They have miles and miles of nets out there, sweeping the ocean clean of our salmon that we try to raise here. And that's what you're going to be doing, is putting some more salmon out for these people to catch. Then the terns have already been mentioned. Our wonderful government made an island out there when they dredged out the Columbia River and made a place for the terns, about 10,000 of them, eating the smolts going out to the ocean. Now that island, I think, ought to be shoved under water and let the terns go elsewhere. Even though they are an "endangered species" when there's 10,000 of them that's not very endangered. Well the Indians, of course when they first had the agreement in the early 1800s it was for sustenance, and the type of nets they had were hand-made and I don't know what they wove them out of, but they got enough fish for

sustenance. Now they claim there are over 700 nets. And somebody flew over and they counted, and said they counted 1,000 nets. Now I don't know how much of that is true or not, but that's what hit the paper. And they have modern nets. They can't be seen in the water, they're almost invisible. They're catching fish way beyond their sustenance because I know I went down the Columbia River each year now for a while for other reasons stopped in there and they were selling the fish for $2 apiece. Now that isn't sustenance. That $2 buys some other things, usually whiskey if I can use the expression. Anyway, that's enough for me to say. Thank you for listening. Any questions? Somebody must have a complaint about what I said.

Frasier Strutzel: I have some comments I would like to make. I'm Frazier Strutzel and I live at Monitor, Washington P.O. Box 259. But I had a real problem with the Endangered Species Act and the National Marine Fisheries Service enforcement of that. And that is the item I brought up before of the Article 3 or 4, whichever one deals with predation, and I see the National Marine Fisheries Service totally ignoring that. They're actually protecting predators. And I think until you enforce all the articles of the Endangered Species Act, and not the ones that serve your bureaucracy and to further your bureaucracy. I think everything you do should be ignored and I think it's a waste of tax dollars. And I personally will contact my senators and representatives and urge them to cut the National Marine Fisheries Services' budget. I think that's the only way you get an agency under control. If you're going to bring this Endangered Species Act out here and club us over the head, you know, I'm paying for all this every time I send in my power bill. I'm paying for all this crap that's going on. And until you folks start enforcing the entire Endangered Species Act, I think you ought to be ignored and your budget should be cut.

Bob Dach: I just thought I would ask. What do you think, for instance, the utility's proposal of this Habitat Conservation Plan?

Frasier Strutzel: How it's made me mad?

Bob Dach: Just what they're putting on the table. Endangered Species Act aside, what they're putting on the table to, in essence, enhance and recovery these species.

Frasier Strutzel: Do I have a problem with my PUD spending these millions of dollars to enhance salmon runs?

Bob Dach: Yeah.

Frasier Strutzel: Not really. No, I'm a conservationist, my family has been farming in Monitor since 1907, and we've done everything we can to enhance the wildlife in our orchard and in the surrounding hillsides of our orchards. Prime hillsides, and we do everything we can to support the wildlife and the bird populations. And we want to see fish in the rivers. I have no problem with money being spent wisely, but when I see it spent of nonsense, which this is, I have a problem with that. But actual money being spent on the turbines to lessen the kill of fish, that's a good one. I'd pay my share of that one anytime. But this bureaucratic nonsense that we're paying for, which this is, I have a problem with it

because you folks are only enforcing the portions of the Endangered Species Act which further your bureaucracy, that's my problem.

Bob Dach: So it's appealing, if I might paraphrase, to have, I guess what can be phrased certainly as a higher level of willful control over how the money is spent. It's not so much that you don't think there is a need there, it's that you think that it would be much more appropriately addressed if you had a little bit more hand in it.

Frazier Strutzel: What I think should happen is that we should get rid of the Caspian Terns with shotguns, if that's what it takes. That would make sense.

Bob Dach: I don't know if I'm allowed to comment.

Frasier Strutzel: I understand what you're saying, but we need to stop the high seas fishing. I have personal friends that fish on the high seas and they say when the nets are pulled in, and there is incidental kills of salmon, the observers onboard the ship turn their heads the other way. There's no count made of that at all. Those fish are uncounted. We actually had a salmon situation here where Rollie Smitten, who I grew up with, working together for salmon, water and people. Rollie Smitten was director or assistant administrator for the National Marine Fisheries Service. I grew up with Rollie, and he came and he said that the fish issue is not happening on the high seas, and I took issue with Rollie. I said I know for a fact that it is because I know guys out there on ships. And it is happening out there. But we're friends and everything but I took issue with him because I know people who are on those boats. And the observers are letting them get away with the incidental kill of salmon. They're pulling in huge, mile-long, miles and miles of nets and there's, one guy saw over 1,500 salmon kicked overboard one day on one ship. There is over 3,500 ships out there. That's not being addressed by you folks, you're here clubbing our dams over the head, you know. Because somebody has an agenda to try to remove our dams. And that's what's being pushed.

Bob Dach: Are there any more questions?

Steve Hays: Well, if nobody else, I would like to go over a few things. I work for the PUD here, you guys own me and if you don't like what I say you can fire me because I'm an at-will employee. I've given about 8 years, a better part of 8 years of my professional career as a biologist here at the PUD working on this plan. So I wanted to make sure that everybody understood exactly what Bob has been explaining here and what the issue is before us. And the real issue is that there are two alternatives out there for dealing with the Endangered Species Act responsibilities the PUD has through the FERC who has responsibilities, particularly in terms of relicensing the Rocky Reach project, for example, we have to deal with these issues. Because if we don't get it dealt with, FERC is the federal agency who has to deal with National Marine Fisheries Service over the Endangered Species Act. So the issue is, what is the best way to approach the problem. National Marine Fisheries Service can talk to FERC, federal agency to federal agency, and Bob went through at the end there the Section 7 process, which is a federal process whereby their action to grant a new license to Rocky Reach, say, is a federal action that requires consultation. National Marine Fisheries will come and consult with the PUD

and with FERC to try and work out a reasonable approach. But at the end of the day, their opinion is the judgment. The other option is the Section 10 permit, which would not just cover the two listed species, but would be a comprehensive package, hopefully with multiple signatories, not just the National Marine Fisheries Service and FERC but the Fish and Wildlife Service, the state Department of Fish and Wildlife and hopefully some tribes and even perhaps an environmental group. All with the combined commitment to make a process work, that they would take care of the ESA issues through a Section 10 permit. They actually have, at least when we all walked out of the room three years ago, felt that they could even give up some of their opinion-type authority and delegate it into the alternative dispute resolution. And allow the seeking of a third, impartial party to get it worked out. So those are the issues, which process do you citizens in this area feel is a better way to resolve a National Marine Fisheries Service mandate to protect these specific species. Regardless of whether they should be listed or not listed or they're not doing enough out there. We only have here at the PUD, control over those things that we can directly affect. We can't affect other than with our votes, we can't affect offshore harvest or something else. I can affect turbines at Rock Island Dam, I can affect turbine survival. That's the issues, is anyone unclear of what the issue is? If your going to comment on the draft environmental impact statement, the comments they're seeking are what alternative you think should be the preferred alternative, Section 7 or Section 10, and why. What do you like about it and what you don't like about it. What do you like about Section 10 or what you don't like about it. If you like the alternative dispute resolution, you would do them a service and us a service by making that comment. If you don't like it you won't do us a service, you'll do them a service by making that comment. And so forth.

Arnold Asmussen: I'd like to answer that directly. This is Arnold Asmussen, the guy with the previous question, I cannot speak for the Methow Basin Planning Unit, and in no way shape or form am I. But I have been involved with them, and we have been negotiating in a similar scenario with that little drainage that you're going through with the dams, and an HCP is on the table for us, as it will be for you. I think local input of any sort given to the PUDs and the ability of the citizens to come to speak to those decisions is good. Those processes appear to have been manipulated by the National Marine Fisheries in terms of timing and different things that they can do to achieve whatever objectives they have. And I'm not saying their objects are bad, we want salmon in the river, we want to see steelhead fishing back at Pateros, not just below Wells Dam and above Brewster, which is in the gap. But the Section 10 will allow us to speak to the issues and that is appreciated. But I would certainly say with a high degree of wariness what you enter in to them because the fact that the citizens get to have input adds validity to the decisions, rather than just the federal agencies making decisions on their own. And you want to make sure that that validity isn't misled.

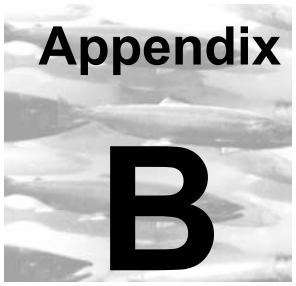
Steve Hays: All I can conservatively say is that none of us three years ago thought that we be at this place in the process that we'd all be walking out of the negotiations with smiles on our faces, but such is life. But at any rate, that's a valid comment that I've heard that concern raised before. Are you better to be part of the process and…..

Arnold Asmussen: You do not want to get in a position where you're being asked to sell the emperor's new clothes. That's a good comparison. When you have to have water, water tables in the Methow going back to pre-date historical man, that's asking an awful lot. And you do not want to get in those positions, I would check and re-check the science and the numbers, but certainly local input is the way to go, I would think.

Steve Hays: So that's all I had to say, I just wanted to make sure that everyone knew what the purpose of today's meeting was, and what the two decisions are with National Marine Fisheries Service and which of the two processes will carry the day when they get through their internal analysis asking themselves whether they can do it this way or not. That's why we want public comment on how it should be approached.

Bryan Nordlund: I just wanted to say that I want to personally thank everybody for showing up here tonight. You know I understand that we've taken some hits, and that's fine. I mean, I'm perfectly willing to listen to public input, especially guys, a lot of you have prepared and I could tell you've done your homework and know the issues as well as you can. I really appreciate the input. The things that we can control, in hydro, our little portion of the ESA world, we're doing to the best of our ability and apologize to those of you who that don't think that we are. I have a passion for trying to protect the fish, I've lived here all my life, I'm a fisherman, I want to see the fish healthy just like you all do. And that's reflected in my work. And I'm here on my own time tonight, and so is Bob and I think so are these guys from FERC. And it's just specifically to solicit public input from people like yourselves that have the same concerns and passions that I do about the fish. So I just wanted to give my personal thanks, not a National Marine Fisheries Service thanks, but my own thanks.

Bob Dach: Again, I'd appreciate any comments that you have to send it to me to the address in that handout. And, no guarantees, but the information can never hurt. You might think we won't do anything with it, but we certainly aren't going to do anything with it if we don't get it.



DEIS Public Comments

Appendix B provides written comments received by the public (including agencies, non-governmental organizations, businesses, and individuals) on the DEIS. Substantive comments in each letter are marked and numbered.

Provided at the front of each letter containing substantive comments is a table directing the reader to the specific NMFS numbered response in Appendix C. The NMFS response may direct the reader to specific FEIS sections that were changed based on the comment or may include a discussion explaining how the HCPs were changed in response to the comment.

Letters without substantive comments are also included in this appendix, although no specific responses were requested by the letter writer. NMFS acknowledges receipt of these letters and the information contained within the letters.

The letters in this appendix are organized in alphabetical order. Refer to the Table of Contents below for the location of specific letters within this appendix.

Mr. Bob Dach
Hydro Division
National Marine Fisheries Service
525 NE Oregon St.
Portland, OR 97232-2737

RE: Comments related to the DEIS for the Wells, Rocky Reach and Rock Island Anadromous Fish Agreements and Habitat Conservation Plans.

Dear Mr. Dach:

The proposed Anadromous Fish Agreements and associated Habitat Conservation Plans represent a milestone in the development of environmental protection and species recovery planning. We encourage NMFS to continue their efforts to find a balance between environ-mental concerns and the need for renewable hydroelectric generation. The HCPs, as defined by Alternative 3 in the Draft Environmental Impact Statement (DEIS), should be selected as the preferred alternative and implemented in its' entirety. The assurances provided in the proposed HCPs include long-term monitoring and evaluations, the guarantee of achieving survival standards and the maintenance of No Net Impact conditions for listed and not-listed anadromous salmonids.

No Net Impact, as defined in the DEIS allows for continued generation of renewable, non-polluting, cost-efficient hydroelectric power while ensuring that important fisheries resources are not harmed. Monitoring and evaluation activities outlined within the proposed HCP will ensure compliance with specified survival standards. Fish populations will be enhanced through the production of hatchery fish and wild fish populations will be augmented through the enhancement of fish habitat found in tributary streams.

In contrast, Alternative 2 should not be selected as the preferred alternative. Alternative 2 covers only spring chinook and steelhead, will result in significant delays in the full implementation of recovery plans and will increase the level of uncertainty concerning future dam operations and power generation .

We are encouraged by the long-term certainty prescribed by the proposed HCPs and anadromous fish agreements. Future certainty in fish recovery planning and in power generation will be important to the future economic viability of the Pacific Northwest.

Sincerely,

Robert D. Huber

RE: Comments related to the DEIS for the Wells, Rocky Reach and Rock Island Anadromous Fish Agreements and Habitat Conservation Plans.

Dear Mr. Dash:

Chelan County is under duress. Many longtime area orchardists, burdened by regulations, market conditions and crop failures, are at or near bankruptcy. Family wage jobs are scarce. New housing starts are at a near standstill. Drought conditions have severely impacted energy supplies. There are problems everywhere you turn.

At Alcoa's Wenatchee Works, one of the area's largest employers, skyrocketing energy prices have forced us to cut aluminum production in half over the past few months. Alcoa's employment levels are scheduled to be reduced this summer, further impacting the struggling local economy.

We are fortunate to have contracted with the Chelan County PUD for a supply of reliable, affordable energy from Rocky Reach Dam -- enough to power approximately two of our five potlines under normal water conditions. Without our long-term contract, Alcoa would likely be unable to continue any level of production at the Wenatchee Works.

Looking to the future, it is absolutely vital that the mid-Columbia Habitat Conservation Plan (HCP) be approved to maintain this area's energy production capabilities and provide cost certainty for Alcoa and all Chelan County PUD customers.

The PUD has demonstrated over the years its outstanding stewardship abilities in protecting the environment while efficiently operating and maintaining its hydroelectric projects. We note that the parties to the HCP have agreed that the PUD has an opportunity to meet established fish survival standards, as opposed to dealing with an endless string of costly mandates imposed by outside agencies.

We have every confidence that the PUD will meet the survival standards. It is worth noting that the PUD has forged ahead, absent an approved HCP, on the installation of a permanent fish bypass system at Rocky Reach Dam.

This kind of commitment demonstrates the PUD's innovation and willingness to meet its regulatory obligations in an aggressive, yet cost-effective manner. The Rock Island Settlement Agreement, construction of the supplementation hatchery and fish friendly turbine installations at Rocky Reach Dam are further examples of the PUD's demonstrated stewardship abilities.

Please consider this letter as a vote of support for the long-negotiated HCP that is outlined in the Draft Environmental Impact Statement. We urge the swift adoption of this program. It is the right approach to protecting both critical energy supplies and the environment.

Re: Draft Environmental Impact Statement: Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects

Dear Mr. Dach:

American Rivers appreciates the opportunity to review the draft Environmental Impact Statement (DEIS) for the proposed Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects, dated November 2000. We strongly support and endorse the comments submitted on behalf of the Save Our *Wild* Salmon Coalition (SOS), and have reiterated and emphasized several specific concerns below.

As noted in the DEIS, American Rivers was involved in the development of a long-term anadromous fish protection plan for the three hydropower projects at issue. It was our goal to ensure that any alternative that allows continued project operations would (1) promote recovery of ESA-listed stocks and make certain that such operations do not jeopardize their continued existence, (2) adequately protect non-listed species and provide sufficient mitigation for the effects of the hydropower projects, and (3) comply with all relevant laws and policy. Prior to resolution of several critical issues and finalization of any plan, Public Utility District No. 1 of Chelan County and Public Utility District No. 1 of Douglas County (collectively, the PUDs) submitted the draft Habitat Conservation Plans (HCPs) to the National Marine Fisheries Service (NMFS) for environmental analysis. The limited analysis contained in the DEIS highlights the failings of the proposed HCPs to adequately protect anadromous salmonids and ensure compliance with relevant federal law and policy. Accordingly, American Rivers does not support the proposed HCPs and urges you to more fully evaluate alternatives that sufficiently protect anadromous salmon and steelhead in the Columbia River basin. The alternatives must be consistent with all relevant federal law and policy.

National Environmental Policy Act

As elaborated on in the comments submitted by SOS, the DEIS falls far short of satisfying the fundamental requirements of the National Environmental Policy Act. NEPA requires that federal agencies take a hard look at the consequences of their actions prior to undertaking them. To do

NORTHWEST REGIONAL OFFICE
150 NICKERSON STREET
SUITE 311

so, agencies must carefully consider the significant environmental impacts of the action, including direct, indirect, and cumulative impacts. NEPA also requires that federal agencies evaluate a range of alternatives to the proposed action, including the alternative of taking no action at all. This alternatives analysis is at the heart of NEPA. The DEIS does not meet any of these requirements for the following reasons:

AR

1 • The DEIS fails to take a "hard look" at all of the environmental information and consequences of each alternative, fundamental purposes of the Act.

2 • The DEIS fails to analyze the cumulative impacts of myriad other actions that affect Mid-Columbia salmon and steelhead.

3 • The DEIS fails to consider an adequate range of alternatives

4 • The DEIS fails to adequately inform the public and decision-makers of the requirements and responsibilities of all federal statutes and treaties.

NMFS may not, as it has done throughout this DEIS, ignore relevant information and rely upon conclusory statements and unsupported assertions to satisfy NEPA requirements. General and speculative statements about hoped for benefits fail to ensure informed decision making, one of the fundamental purposes of NEPA. Consideration of a range of reasonable alternatives to the proposed action is a critical component of any NEPA analysis. However, NMFS effectively evaluates only two alternatives, admitting that the no action alternative would violate the ESA. NMFS must explore and objectively evaluate an adequate range of alternatives including a true no action alternative that considers no project conditions, drawdown, and non-power operations,

5 to name a few. Also, NMFS must consider an alternative that would provide greater protection for salmon and steelhead than the proposed action. While such alternatives may cost more, the DEIS presents no information for the decision-maker or the public to draw any conclusion about the benefits, or cost of such a measure.[1]

6 Finally, the cumulative impacts analysis fails to consider a myriad of easily identifiable, foreseeable actions that affect Mid and Upper Columbia River salmon and steelhead. For example, NMFS must analyze the proposed Columbia River channel deepening project, the Lake Chelan Hydroelectric Project, and numerous other land management activities in the basin.

We believe that these deficiencies present an inaccurate picture of the impacts to the public, making it impossible for anyone, including NMFS, to draw any reasoned conclusions about the environmental impacts of the three alternatives presented in this DEIS.

Endangered Species Act

To echo SOS' comments, NMFS' analysis in the DEIS is wholly insufficient to comply with the underlying legal obligations of the Endangered Species Act (ESA), 16 U.S.C. §§ 1531 *et seq.*

---

7 [1] The DEIS states that the "purpose of the HCPs is to protect fish in the Mid-Columbia River while generating electricity." DEIS at 1-3. This statement too narrowly cabins the rest of the analysis by removing, among other things, consideration of a true "no action" alternative as well as assumes that the HCPs analyzed in Alternative 3 are the proper means to comply with the ESA. We believe that the purpose and need must be expanded to emphasize protection of listed species and compliance with the requirements of the Endangered Species Act as the purpose of this DEIS. The HCPs are only a proposal to meet the requirements of the ESA, they are not an end in themselves. Indeed, to perform a valid NEPA analysis, NMFS must not assume, as it does in the current purpose and need statement, that the HCP Alternative fulfills the mandates of the ESA.

The ESA is the "most comprehensive legislation for the preservation of endangered species ever enacted by any nation." *TVA v. Hill*, 437 U.S. 153, 180 (1978). "[T]he language, history, and structure of the legislation . . . indicate[] beyond a doubt that Congress intended endangered species to be afforded the highest of priorities." *TVA*, 437 U.S. at 174. As a result, agencies are required to use "all methods and procedures which are necessary," 16 U.S.C. § 1532(2), to "*prevent* the loss of any endangered species, regardless of the cost." *TVA*, 437 U.S. at 188, n. 34. The DEIS does not meet that standard and in fact, if implemented would result in serious harm to listed species in the Mid-Columbia. The DEIS violates the ESA for several basic reasons:

- The DEIS violates the fundamental principle of species conservation – erring on the side of caution in the face of uncertainty.
- The DEIS misunderstands the requirements of the ESA.
- The DEIS fails to analyze inconsistencies between Section 7 consultation requirements and the proposed Section 10 Incidental Take Permit and Habitat Conservation Plan.

8 First and foremost, NMFS repeatedly fails to ensure that uncertainty is resolved in a manner that does not place the species further at risk. Of particular concern is the failure to provide the benefit of the doubt to species with respect to data gaps or information disputes. NMFS' approach undertaken in the DEIS is at odds with the cautionary approach required under the ESA. Any risk must be borne by the projects, not by the listed species. The ESA does not allow for an alternative that provides substantial certainty for the project, while placing the risk of uncertainty on the species.

9 Second, the ESA requires NMFS to consider alternatives that are more protective of fish than the HCP. Failure to do so violates the ESA requirement that take of listed species be minimized and mitigated to the "maximum extent practicable." One possible alternative includes drawdown, which NMFS incorrectly maintains is available only at relicensing.

10 Finally, the DEIS fails to analyze a critical issue raised in some of the scoping comments – that the Section 10 incidental take permit process is available only for non-federal actions. NMFS' Habitat Conservation Planning Handbook maintains that the Section 10 process is intended to address non-federal actions that are not otherwise subject to Section 7 consultation. As such, the Section 10 ITP and HCP process may not even be an available option to the PUDs. Although hydropower projects are owned by non-federal entities, FERC clearly maintains ongoing authority and jurisdiction over the project. This ongoing authority constitutes federal agency action, requiring FERC to initiate consultation under the ESA. Although this procedural analysis was not undertaken during development of the HCPs, the DEIS must address the applicability of Section 10 to the FERC-licensed hydropower projects in question.

11 If such an option is available, it does not relieve FERC of its ESA Section 7 responsibilities to insure that the action is not likely to jeopardize the continued existence of any endangered or threatened species. As such, the ITP and HCP must be consistent with FERC's Section 7 obligations. To ensure consistency, FERC must undertake consultation prior to further development of the HCPs.

Federal Power Act

12 The DEIS fails to adequately analyze statutory requirements of the Federal Power Act despite the intention that the HCPs supercede existing FERC license articles and satisfy NMFS' obligations pursuant to sections 18, 10(a), and 10(j) of the FPA. The FPA requires that the commitment of a

river to power production be reevaluated anew at the time of relicensing and establishes various legal obligations that must be met prior to relicensing. The DEIS fails to analyze any of these requirements, and the fundamental nature of the HCP precludes fulfillment of some.

The DEIS fails to consider the following Federal Power Act requirements:

- The DEIS fails to analyze the requirements necessary for the HCPs to supercede the existing FERC license articles and satisfy NMFS' obligations pursuant to sections 18, 10(a), and 10(j) of the Federal Power Act.
- The DEIS and HCPs limit the requirement that a hydropower project licensee evaluate pre-project conditions as required by the Federal Power Act and NEPA.
- The DEIS provides no analysis of whether the HCPs at issue satisfy the FPA.
- The HCPs' "no surprises" assurances presuppose the term and content of the PUD FERC licenses and are inconsistent with reopener clauses intended to ensure "equitable treatment for fish and wildlife over the terms of the license agreement."

Clean Water Act

13 To reiterate SOS' comments, the DEIS provides no analysis of Clean Water Act requirements. The CWA requires that all federal agencies "having jurisdiction over any property or facility . . . shall be subject to and comply with" all applicable federal, state, and local water quality laws. 33 U.S.C. § 1323. As a federal court has recently held, dams are no exception to this rule. *See National Wildlife Fed'n v. U.S. Army Corps of Engineers*, 92 F. Supp.2d 1072 (D. Or. 2000) (holding that the Corps' dams on the lower Snake River must comply with state water quality standards). Further, NMFS' issuance of an incidental take permit or incidental take statement will require certification under section 401 of the CWA. In light of these requirements, the DEIS is deficient in several respects.

- The DEIS lack any analysis of whether the alternatives will comply with water quality standards.
- The DEIS fails to discuss section 401 certification requirements.

NMFS must analyze the water quality impacts of the hydropower projects at issue – Rocky Reach, Rock Island, and Wells – and ensure compliance with the relevant water quality impacts.

Inadequacy of HCP Provisions

The fundamental principle set forth in the HCP is a "no net impact" standard for salmon and steelhead protection at the hydropower projects. This standard consists of two key components – a 91 percent total project survival rate, including an independent 95 percent juvenile passage rate, and 9 percent compensation through hatchery and tributary improvement programs. The DEIS clearly highlights but overlooks the shortcomings of the proposed standards in the HCP. The serious shortcomings place unacceptable risk on the species contrary to ESA requirements, and fail to sufficiently protect salmon and steelhead.

- The DEIS analysis of adult and juvenile survival standards is insufficient. There exist no scientifically credible methodologies to evaluate survival for all covered species at all life stages.
- The DEIS lacks adequate analysis of the off site mitigation proposals – Tributary Improvement Fund or Hatchery Supplementation Program.
- Inconsistencies between the QAR and the DEIS call the DEIS analysis into question

American Rivers would like to reiterate and emphasize the inadequacy of the HCP provisions as outlined in SOS' comments. In particular, we view the inability to measure the proposed survival standards and the inadequate data to support the independent programs as some of the most significant shortcomings of the HCP. And, although acknowledged in the DEIS, NMFS utterly fails to address these issues. Recent actions undertaken by Chelan County PUD highlight the risk that immeasurable standards place on the species. Chelan County PUD based its decision to forego the minimum spill requirement at the Rocky Reach Hydroelectric Project on limited analysis of yearling spring chinook and steelhead. Although not allowed under the HCP, Chelan County PUD relied on representational studies to support its decision. Development of agreed-upon methods for assessing compliance with survival standards for all species must occur prior to implementation of the HCPs.

14

The DEIS acknowledges that there are limited or no methodologies for assessing juvenile and adult survival for all species and all life stages. NMFS cannot issue an ITP while at the same time expressly acknowledging an inability to determine whether the applicant is in compliance with its terms. Moreover, the ESA requires that NMFS resolve uncertainties and information disputes in favor of the species of concern, contrary to what the HCP currently provides. Until the PUDs complete accurate assessments of juvenile and adult survival, the ESA's cautionary principle prohibits NMFS from assuming that the survival rate estimates in the HCP are correct. The DEIS provides insufficient data to support the estimates.

The DEIS also fails to consider the effect of (1) maintaining a 95 percent juvenile dam passage survival standard over only 95 percent of the run, and (2) excluding spring migrating chinook smaller than 50 mm in length from the 95 percent juvenile dam passage survival for the full run of that species in the event turbine intake screens are installed certain instances.

Further, the DEIS provides insufficient evaluation of the tributary habitat improvement or hatchery supplementation program, both of which are key to attaining the no net impact standard. The DEIS acknowledges that there are no means to assess the benefits from these programs and then simply assumes that the funding and supplementation levels contained in the HCPs are adequate. There is no data to support the proposed funding levels for the tributary habitat fund, and NMFS acknowledges that there is no way to assess whether the tributary program is actually providing 2 percent compensation. While a habitat restoration program is critical to salmon recovery efforts, it must be accompanied by measurable goals and objectives. The DEIS also provides no scientific justification for reducing Douglas County PUDs contribution to the habitat fund in the event it achieves a 95 percent juvenile dam passage survival rate at Wells dam.

15

Similarly, the DEIS provides insufficient analysis of the proposed hatchery program, other than to assert that it must be consistent with ESA recovery goals. The DEIS fails to explain how such consistency may affect the program and its ability to provide 7 percent compensation. Although unable to guarantee 7 percent hatchery compensation, NMFS fails to analyze the effect of not meeting the 7 percent, and in turn, the no net impact standards.

16 Finally, the Quantitative Analytical Report (QAR) relies on several unjustified assumptions in its analysis. There is no data to support that (1) the survival improvements that the HCPs call for at the hydroprojects, and through off-site mitigation, occur instantaneously, (2) Grant County PUD's Priest Rapids Project has achieved a 95 percent juvenile survival standard, and (3) the survival improvements called for in the Federal Columbia River Power System Biological Opinion are being met. Inconsistencies between the QAR and available facts call into question NMFS' reliance on the analysis to draw any conclusions about the adequacy of the HCPs.

All of this adds up to insufficient protection for salmon and steelhead. The significant uncertainty associated with the HCP standards (95/91/7/2 percents), coupled with an inability to determine compliance, is inconsistent with ESA requirements and precludes NMFS from fully assessing the environmental impacts of the HCPs.

Conclusion

The DEIS fails to demonstrate that the proposed HCPs provide sufficient protection to Columbia River Basin salmon and steelhead that are negatively affected by the hydroelectric projects. Moreover, the DEIS highlights the significant shortcomings of the HCPs and their failure to comply with all relevant federal law and policy. American Rivers does not support these long-term salmon and steelhead protection plans. The limited analysis in the DEIS in no way justifies issuance of incidental take permits that will lessen NMFS' ability to undertake whatever actions are necessary to protect and recover listed species for the next 50 years.

Thank you for the opportunity to comment. Please feel free to call if you have any questions regarding these comments.

Sincerely,

Brett Swift

CLYDE BALLARD
REPUBLICAN SPEAKER OF
THE HOUSE

State of
Washington
House of
Representatives

FEB 14 2001

RULES
CO-CHAIRMAN

February 12, 2001

Northwest Region - Hydro Program
National Marine Fisheries Service
525 NE Oregon St. Suite #420
Portland, OR 97232-2737

Dear Sirs:

Affordable, reliable electricity has been the lifeblood of Washington's state's economy for decades. Fueled largely by clean, renewable energy from hydroelectric power, our state as a whole has been able to grow and prosper. Now, hydroelectric power is in short supply. Environmental regulations have all but eliminated new hydropower plant construction, and conditions imposed on existing power plants have significantly reduced generation. Our state faces an immense challenge in finding new generation sources to fuel an expanding economy.

In many rural Eastern Washington communities, affordable hydroelectric power is not only critical for growth, it is critical for survival. The agricultural industry is in serious decline, in part due to the cost of endless regulations imposed by unyielding agencies. Aluminum plants are closing or severely cutting production due to rising energy costs. Jobs are in short supply.

For several years, I have been closely watching the development of the Habitat Conservation Plan (HCP for the hydro projects in the mid-Columbia area. Frankly, I have been disappointed that we have all had to wait so long for this plan to wade through the regulatory process. We cannot afford to wait any longer.

The HCP offers hope that the mandates of the Endangered Species Act can be met, while retaining critical hydroelectric power supplies. Rather than relying upon agencies to mandate never-ending fish protection measures, the plan establishes an outcome-based standard. The Public Utility Districts (PUDs) have the opportunity to meet the agree-upon survival standards, with unavoidable losses compensated through state-of-the-art hatchery production and habitat funding.

Finally, we may have a model for addressing fishery protection that embraces common sense. It's about time.

I would like to note for the record that our PUDs have not been waiting for the regulatory review process to conclude before moving ahead with resource portection plans. For example, Chelan County PUD has thoroughly tested a prototype surface collection system at Rocky Reach Dam. Construction of a permanent surface collector will begin later this year. The PUD is also nearing completion of a turbine replacement project, using a more fish-friendly design. The cost of these programs is significant and the PUD should be applauded for its environmental stewardship.

I support the HCP and urge you to move it swiftly through the review process. This is a golden opportunity to demonstrate to the citizens of Washington State that cooperation can yield positive results. Our citizens are growing more and more skeptical that something like this is possible. Don't disappoint them.

With Warmest Regards,

CLYDE BALLARD
Speaker of the House

To Whom It May Concern:

Collaboration is one of the best lessons we can teach.

When we're facing a challenge as difficult as protecting salmon and steelhead in the Columbia River, it is remarkable to find a solution such as the Mid-Columbia Habitat Conservation Plan. The fact that it is a negotiated effort in an arena marked by adversarial action provides a valuable template for the future.

I endorse the plan for these reasons:

* It ensures protection of salmon and steelhead while maintaining an economical and reliable energy supply for our region.
* It establishes performance standards, based on the best available scientific evidence and allows local PUD fisheries staff to develop the most cost-effective ways to meet them.
* The plan provides a balanced approach to compensation for unavoidable losses.
* It includes a commitment to improve habitat in the Columbia River as well as important tributaries such as the Wenatchee River, a touchstone of our town.
* A dispute resolution process is included to avoid expensive and time-consuming legal battles that would take resources away from helping fish.

Overall the Mid-Columbia Habitat Conservation Plan is a much needed, innovative and rational approach to protecting endangered salmon and steelhead while also ensuring continued operation of our local hydroelectric dams. That power source is crucial to the region to ensure there will be jobs for our students in the future. This is particularly true because our agricultural industry is eroding.

Sincerely,

Lynn W. Baker, Ed.D.

To Whom It May Concern:

As a lifetime resident of North Central Washington who is currently serving as the President of Cashmere Valley Bank, a six branch community Bank with headquarters in Chelan County, I have deep concerns regarding our local economy. The performance of a community bank is the reflection of the success or failure of the customers it serves.

Currently our agricultural based economy is suffering serve setbacks as it deals with the challenges of pesticide use, land use restrictions, water regulations and Federal trade policy. The financial difficulty is resulting in numerous bankruptcies and beginning to impact our unemployment rates, retail sales volume and housing industry.

One of the strengths of our local economy is the dependable, reasonably priced supply of electricity provided by the Chelan County Public Utility District. But they are experiencing increasing costs from salmon and relicensing projects. Sooner or later those costs will need to be pasted along to the local customers. I have grave concerns over the impact of those increases on our local economy.

It is because of the need for the dams to continue to provide reasonably priced power that I support the habitat conservation plan for our PUD's dams on the Columbia River.

Although I am not an expert on the HCP, I understand that it address the mandates of the Endangered Species Act in a logical and reasonable manner. I believe we will be best served by giving our PUD the survival targets and let them decide on how to best meet them. I believe that hatchery programs and habitat improvements are the best way to supplement fish losses. Local control with reasonable oversight makes the most sense to me.

As a banker I understand the impact of regulation on our ability to do what is best for our customers. These regulations are often born of good intention and end up having exactly the opposite of the intended impact. Please don't let this happen to our PUD as they work diligently doing what is best for fish and the best for our local power supply.

Sincerely,

Ken Martin

National Marine Fisheries Service
Northwest Region – Hydro Program
525 N.E. Oregon Street, Suite 420
Portland, OR 97232-2737

To Whom It May Concern:

Central Washington Hospital in Wenatchee and our power provider, Chelan County Public Utility District, share the challenge of providing a vital service at a reasonable cost for our community. As the head of a regional, non-profit hospital, I oversee a team striving daily to accomplish this, even though factors outside our control often drive those costs.

This is why I support the Mid-Columbia Habitat Conservation plan negotiated by Chelan and Douglas County PUDs. It would provide a measure of financial certainty for the complex proposition of protecting and enhancing salmon and steelhead in our region. Its performance-standard approach provides an incentive to find a cost-effective solution, based on the best science available. That ensures a benefit not only for fish, but our region as well, by providing a balanced approach to compensation for an unavoidable loss.

I also endorse the Habitat Conservation Plan's collaborative approach, which includes a method for resolving future disputes and avoids the lengthy governmental processes that can lead to long and expensive legal battles. The plan also provides a guarantee – something that can be hard to come by in these challenging times – of no net impact on fish from the PUDs' hydropower operations. If Chelan and Douglas County PUDs fail to meet that standard within five years, then the regulatory agencies have a guarantee the PUDs will put the agencies' recommendations into place quickly.

In conclusion, the Mid-Columbia Habitat Conservation plan offers a cost-effective process, based on the best scientific information available for protecting the Northwest's salmon and steelhead, and I urge your approval of this innovative approach.

Sincerely,

John T. Evans, Jr., FACHE

January 29, 2001

National Marine Fisheries Service
Northwest Region - Hydro Program
525 NE Oregon Street, Suite 420
Portland, OR 97232-2737

In our capacity as the elected officials representing the citizens of Chelan County, we are writing to support the mid-Columbia Habitat Conservation Plan (HCP).

Over the past several years, we have literally seen our local government and our citizens strangled by endless federal and state regulations. Our once-plentiful and prosperous orchards are being plowed under because their owners are finding it impossible to make a profit. Government regulations have played a major role in this catastrophe.

Other landowners are also hampered by too many rules and regulations. Substantial amounts of privately-owned land can't be developed due to water rights issues, setback requirements, required lot sizes or other concerns.

The HCP offers some hope that diverse interests can work together and craft workable solutions to address challenging environmental and regulatory issues. It includes a measure of certainty that our hydroelectric dams can continue operating in a cost-effective manner, while meeting fishery obligations mandated by the ESA.

Our county and its economic future rely heavily upon hydroelectric power. With a per-capita income half that of the Seattle area and with unemployment at nearly double-digit levels in Chelan County, we desperately need the affordable energy that the Chelan County PUD provides through ownership of its Columbia River dams.

The outcome-based approach outlined in the HCP makes great sense as opposed to the traditional method of endless mandates with no accountability and a lack of clear goals. The HCP approach sets survival standards to be achieved by the PUD at its dams. The PUD has the expertise to develop cost-effective fish protection and enhancement

programs while maintaining critical operating standards. They have demonstrated their stewardship countless times, most recently with the unique, new surface collection system at Rocky Reach Dam.

We also applaud the approach to compensating for unavoidable losses. The fund provided by the PUD will address some of the critical habitat improvement needs in Chelan County. Those needs are among the items being discussed by Chelan, Douglas and Okanogan counties and the Colville and Yakama tribes as we work on the Upper Columbia River Salmon Recovery Board to formulate recovery planning for our area. The fund may also provide habitat recovery program partnership opportunities.

We support the HCP and urge a fast-track approach to its adoption. Thank you for the opportunity to comment.

Re: Habitat Conservation Plan

Gentlemen:

The Chelan County Granges have reviewed the "Anadromous Fish Agreements and Habitat Conservation Plans" prepared by the Chelan County Public Utility District #1 dated November 2000. The Granges find Alternative #3 to appropriately and adequately address the environmental impact including the protection of anadromous fish species and non-threatened species and to allow continued operation of the three dams to provide power, recreation, and other uses for the human species.

The Grange has always been a proponent of sound environmental policies and procedures and conservation of our natural resources. We also believe an adequate supply of electrical energy at a reasonable cost is absolutely necessary to allow continued economic viability of the region. Therefore, some compromise is essential to balance the requirements of the resources necessary for people with those of fish and other wildlife.

We strongly encourage you to approve the proposed alternative #3 in the process of re-licensing the Mid Columbia dams and issue the incidental take permits authorized under Section 10 (a)(1)(B) of the Endangered Species Act.

Also for your information, we are attaching a document developed by the Chelan County Pomona Grange in 1992 which reflects the Grange's past as well as its current position and concern on the issue of salmon recovery.

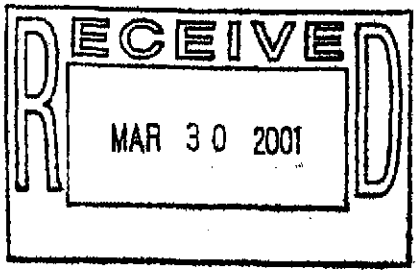
LAND TRUST

Preserving our lands for generations to come



March 28, 2001

National Marine Fisheries Service
Northwest Region – Hydro Program
525 N.E. Oregon St, Suite 420
Portland, OR 97232-2737

To Whom it May Concern,

I have reviewed the Draft EIS for Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects. I strongly support Alternative 3, the proposed HCPs for Rock Island Dam, Rocky Reach Dam, and Wells Dam. I am familiar with the provisions of the Endangered Species Act (ESA) and believe that the development of these HCPs is the only practical way for Chelan and Douglas PUDs to meet the requirements of the ESA. I complement the PUDs on their proactive approach to meeting the requirements of the ESA. This is a bold and progressive step that demonstrates true leadership.

Let me make it clear that the Chelan-Douglas Land Trust (CDLT) is not simply an interested observer. The CDLT is actively involved in the protection of salmon habitat and other fish and wildlife habitat in North Central Washington. We recently received nearly $1.5 million from the Salmon Recovery Funding Board to purchase salmon habitat along the Entiat River and we will be applying for additional money from the Salmon Recovery Board in the future. We are developing the capacity and expertise to own properties and easements and manage them for their habitat values. It is likely, therefore, that the CDLT can play an important role in the proposed Tributary Conservation Plan.

CDLT

1 Now that you know where I am coming from, let me state the CDLT perspective on some of the specifics of the Draft EIS. I would rather see the compensation for unavoidable project mortality come more from the tributary program and less from the hatchery programs. The tributary program will provide numerous public benefits above and beyond improving salmonid spawning and rearing habitat. However, I know this is a very difficult and contentious issue. I will support the proposed 7 percent compensation through hatchery programs and 2 percent through habitat improvement programs. The hatchery program should be closely monitored however. On a

2 recent tour of Columbia and Methow River hatcheries I observed firsthand that hatcheries require careful evaluation and monitoring. Otherwise they can become institutionalized commodity production facilities that churn out fish like widgets with little regard for their

genetic makeup and unique life histories. Hatcheries should enhance natural reproduction not attempt to replace it.

3 I also hope that the funds in the Plan Species Account will be spent prudently and in conjunction with other salmon recovery efforts. Chelan, Douglas, and Okanogan counties have developed an outstanding regional process for evaluating projects submitted to the Salmon Recovery Funding Board. Their efforts helped entities in this region to garner nearly $5 million in the latest round of Salmon Recovery Funding Board grants. The proposed Tributary Committee should work closely with this existing group, rather than duplicating their efforts.

4 I also believe that that a majority of the funds in the Plan Species Account should be spent sooner rather than later. There is an urgent need to protect critical habitat now, before it is further subdivided and degraded. With the decline in the orchard economy, many of the orchards along the tributaries will be put up for sale in the next two years. This presents a unique opportunity to acquire property or easements to protect riparian areas and floodplain along the tributaries. Some of the funds in the Plan Species Account also need to be dedicated to the long-term maintenance of these properties and easements. If the CDLT should end up acquiring properties or easements with these funds, we would require that a certain percentage of the funding be dedicated to long-term maintenance. I also recommend that funding be set aside to

5 make property tax payments or payments in lieu of taxes. There will be strong opposition to protecting habitat along the tributaries if this means the properties are removed from the tax rolls. Providing funding for tax payments will make this effort much more acceptable to local citizens and elected officials.

I recognize that there is strong opposition to HCPs from all sides of the political spectrum. Conservation groups argue that HCPs are a sellout and not enough is known about the affected species to make such long-term agreements. While I acknowledge these as valid concerns, I believe that there is more to be gained than lost by the implementation of the proposed HCPs. With the recent HCP revisions (June 1, 2000) that clarify the importance of biological goals, adaptive management, monitoring, permit duration, and public participation, I feel confident that the proposed HCPs can be evaluated and monitored to make changes when appropriate. I therefore strongly support the HCPs as proposed in the Draft EIS.

Yours sincerely,

Gordon H. Congdon

Dear Sir or Madam:

As mayor of Cashmere, WA, located on the shores of the Wenatchee River, I am very familiar with the competitive interests laying claim to the water of our rivers and streams. Farmers, fishermen, environmentalists, river rafters, power producers … all have a vested interest in our water.

These competing demands frequently result in stalemates at best and court battles at worst. The Habitat Conservation Plan forwarded by Chelan County PUD takes a new approach, and I commend the PUD for its vision.

The HCP offers a common-sense plan for alleviating the fish problem. The HCP sets fixed targets for fish survival, allowing the PUD some freedom in how to meet those targets. Yet it includes regulatory oversight that should satisfy both environmentalists and the various federal and state agencies. It creates a spirit of cooperation not evident in many, many other water issues.

I also strongly support the focus on habitat, since the Wenatchee River is a Columbia River tributary that could stand to gain under the HCP program.

The PUD supplies wholesale power to Cashmere and is an important player in the economic health of our region. The HCP allows the PUD to do what it has always done best -- generate power -- while providing for continued mitigation and enhancement of the local fishery.

I urge you to move ahead on the HCP process.

Sincerely,

Gordon Irle
Mayor

City of Entiat
Washington

March 12, 2001

To Whom It May Concern:

As Mayor of a community situated along the reservoir created by Rocky Reach Dam, I am directly aware of the importance of balancing river uses.

The City of Entiat relies on tourism created by having an attractive waterway for recreation; on the economic benefits of a sustainable sport fishery; on the use of water to irrigate the fruit orchards within and surrounding the community and on the economic boost afforded our financially stressed region by low electric power rates made possible by Rocky Reach Dam. Implementation of the Habitat Conservation Plan (HCP) will help preserve all of these benefits.

Chelan County PUD has demonstrated how well it knows the business of running its' dams, and the sizable expenditures and endless work on fish protection over the last 20 years are equally significant. With the cooperative approach envisioned by this HCP, there is every reason to believe all the critical resources will be protected long into the future.

On behalf of the City Council of Entiat, I compliment all the participating agencies on the work that went into creating this Habitat Conservation Plan. We support the provisions it contains and recommend their implementation as quickly as possible.

Sincerely,

Wendell Black

Portland, OR 97232-2737

After discussion with the City Council, I am writing in support of the Chelan County PUD's Habitat Conservation Program (HCP) now under review by your agency.

Since a national fish hatchery is located in our back yard (on Icicle Creek, a tributary of the Wenatchee River in Chelan County), most citizens of Leavenworth are keenly aware of the issues surrounding salmon survival. They know about the competing demands on our rivers and streams – demands for domestic water, irrigation, hydro generation, fisheries and recreation, among others. They are also aware of the stalemates that can result when these seemingly competing interests are at legal loggerheads.

The proposed HCP offers a common-sense approach to the fish problem. The HCP gives Chelan County PUD a fixed target, the outcome-based standard of 91 percent overall survival It allows the PUD time to find the most economical means of satisfying the regulatory agencies' fish protection requirements. And it appears to avoid the courtroom, where so many of these issues end up.

Of particular interest to the citizens of Leavenworth are the provisions for habitat protection and improvements included in the HCP. Leavenworth is situated near several important tributaries to the Columbia River, and we support habitat improvements to these rivers and streams.

On the business side, I represent a community that has become an outstanding pillar of the tourism industry of the Pacific Northwest. More than one million (1,000,000) visitors come to Washington's Bavarian Village each year. It is our hope that the PUD will be allowed to continue as the provider of low-cost, reliable electricity while maintaining its status as a good steward and good neighbor.

Please place the City of Leavenworth on record as supporting the Habitat Conservation Plan (HCP) of Chelan County PUD.

Sincerely,

William J. Bauer

National Marine Fisheries Service
Northwest Region – Hydro Program
525 N.E. Oregon Street, Suite 420
Portland, OR 97232 – 2737

Dear Sirs:

We would, on behalf of the citizens of Wenatchee, like to collectively voice our support for the mid-Columbia River Habitat Conservation Plan (HCP).

Our community relies heavily upon affordable, reliable hydroelectric power. Public Utility District (PUD) dams therefore provide the foundation for the local economy, which has been struggling for the past several years due to extremely unfavorable agricultural market conditions and intense regulatory pressure. We must maintain the economic stability provided by hydroelectric power to preserve an affordable lifestyle for our citizens and to attract new businesses to the Wenatchee area.

The HCP is a carefully planned, collaborative approach to protect mid-Columbia fisheries resources. By establishing performance standards rather than arbitrary mandates, the HCP provides a measure of business certainty for the PUD and its customer owners while ensuring that effective, scientifically-based fish protection measures are implemented.

The City applauds the Chelan County PUD for not waiting until the conclusion of the HCP regulatory process to start implementing such fish protection measures. At Rocky Reach Dam, for example, testing of a fish collection and bypass system is nearing completion, with the permanent system scheduled for installation next year. This work is a vital part of meeting the fish survival standards outlined in the HCP.

The HCP provides a common sense model for addressing the requirements of the Endangered Species Act, and provides a far more productive approach than court system battles of regulatory disputes. We are hopeful that other jurisdictions will embrace this model throughout the region, as we all must do our part to save our salmon.

It is our understanding that the HCP outlines fish survival standards at the hydroelectric projects, with compensation for unavoidable losses to be provided by a PUD-funded conservation account. We believe this is an excellent idea, as it may provide an avenue for future partnerships with other government entities and organizations for matching funds to address critical habitat areas.

We are hopeful that the HCP will move swiftly through the regulatory review process and that its terms and conditions will be implemented as soon as practical.

Sincerely,

Dennis Johnson

RE: **Comments on the Mid-Columbia Habitat Conservation Plan Draft Environmental Impact Statement**

Dear Ms. Darm:

The Columbia River Inter-Tribal Fish Commission (CRITFC),[1] on behalf of the Confederated Tribes and Bands of the Yakama Nation (YN), the Confederated Tribes of the Umatilla Indian Reservation (CTUIR), the Confederated Tribes of the Warm Springs Reservation of Oregon and the Nez Perce Tribe has reviewed the document entitled, "Anadromous Fish Agreements and Habitat Conservation Plans-Draft Environmental Impact Statement for the Wells, Rocky Reach and Rock Island Hydroelectric Projects" (DEIS). We have prepared the following comments. We also include by reference the comments of the Yakama Nation and the Confederated Tribes of the Umatilla Indian Reservation on the DEIS. We appreciate NMFS granting us additional time to comment on the DEIS.

Overview

The Yakama Nation and the Confederated Tribes of the Umatilla Indian Reservation aboriginally occupied lands in what is today the Mid-Columbia region in Washington State. The Columbia River and its tributaries are a part of that land. Protection of rivers and flows for anadromous fish and wildlife populations, as well as cultural resources and other matters are critically important to these tribes. The existence and operation of the Wells, Rocky Reach and Rock Island Hydroelectric Projects impacts the treaty-reserved natural resource interests of all four CRITFC member tribes. The outcome of the DEIS process could significantly affect rebuilding of fish and wildlife populations impacted by the Project. Therefore, the tribes have a unique interest and stake in this process that cannot be represented by any other entity.

[1] The CRITFC was formed in 1977 per formal resolution of the governing bodies of the four Columbia River treaty tribes: the Yakama Nation, the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes of the Warm Springs Reservation of Oregon and the Nez Perce Tribe. The Commission is comprised of elected and appointed tribal officials who are members of the respective tribal fish and wildlife committees. The Commission has technical and legal resources that provide assistance to the tribes in protecting and enhancing their federally reserved trust resources.

Anadromous fish stocks that originate above and within the boundaries of the Wells, Rocky Reach, and Rock Island Projects (Projects) are adversely affected by the presence and operation of the Projects. These stocks support ceremonial, subsistence and occasional commercial treaty fisheries in Lower Columbia River Zone 6 by all of the CRITFC member tribes. Thus, CRITFC has a unique interest in this process that cannot be represented by any other party.

DEIS Scoping

In general, CRITFC notes that NMFS has failed to address most of the CRITFC February 5, 1999 comments and recommendations made to the DEIS Notice of Intent to Prepare an Environmental Impact Statement (EIS) on the Habitat Conservation Plans (HCPs) for the Operation of the Projects (NOI). We incorporate by reference into the record the CRITFC February 5, 1999 comments on the NOI (Attachment 1). The purpose of scoping for a NEPA environmental impact statement is to collect a reasonable range of alternatives to be reviewed and analyzed in the statement. We note that the following critical issues included in the scoping comments are not addressed in the DEIS. This is not an exhaustive list of issues raised in the CRITFC comments on the NOI:

CRITFC

1

- The HCP hatchery plan attachment and the no-net impact standard, the foundation of the HCP Agreement, was contingent on the tribes receiving reciprocal assurances relative to treaty-secured fishing rights. The DEIS maintains NMFS position of not guaranteeing that the hatchery component will be met, thus, the no-net impact standard cannot be met.

2

- Other issues between the tribes and NMFS relative to reserved treaty fishing rights, such as potential prejudice against tribes posed by the "no surprises rule," also remain unresolved in the DEIS.

3

- The DEIS did not correct the misleading language of the NOI that states that parties to the 1998 "Commemorative Declaration" signed a declaration acknowledging "*their commitment to complete the regulatory actions necessary to issuing a permit*" (emphasis added). The Declaration did not commit the parties to this language.

4

- The geographic scope should not be limited to the three project area, but should be a reach-based approach consistent with the original intent of the HCP, including the federal projects, Grand Coulee and Chief Joseph, the Priest Rapids Project and the Hanford Reach. In particular, the existence and operation of federal projects above the three Mid-Columbia Projects significantly influences flow management and water quality, which in turn impacts anadromous fish survival through the Projects. This remains a major deficiency of the DEIS.

5

- The DEIS fails to address anadromous fish survival and recovery from a life history and ecological perspective (Williams et al. 1996; Lichatowich

and Mobrand 1995). Anadromous fish productivity cannot be addressed merely by measuring direct survival of a small sample of salmon from one point above the Projects to a point below the Projects.

6 • A cumulative impacts analysis is lacking in the DEIS.

7 • The DEIS should not have used the existing degraded state of salmon stocks and critical habitat as the environmental baseline, but should have used the natural river baseline as the measuring stick for considering harm and benefits. The DEIS should have taken into consideration the fact that the development of hydroprojects in the Mid-Columbia Reach set in motion a decline in fish populations that continues through much of the Columbia River Basin. NMFS themselves argued for use of a natural river baseline in American Rivers et al. v. Federal Energy Regulatory Commission 201 F.3d 1186 (9th Cir. 2000), but has not used this standard in the DEIS.

8 • The DEIS failed to include Pacific Lamprey and sturgeon in the "Plan Species". Current and permanent development of a screened bypass system, under "conditional HCP implementation"[2] at Rocky Reach does not consider lamprey passage, and lamprey have shown a propensity to become impaled upon screen systems at other basin dams (ISAB 98-4 1998).

9 • The DEIS failed to review and acknowledge water quality standards under the Clean Water Act. A recent court opinion states that dams are not above the law with respect to meeting water quality standards (see National Wildlife Federation v. Corps of Engineers, 132 F.Supp.2d 876 (D. Or. 2001).

10 • The DEIS lacks an adequate quantitative analysis as to how much take of the listed species will occur under the proposed alternatives. Further, the DEIS fails to quantify the effects that each proposed alternative would have on the goal of reaching sustainable anadromous fish populations that provide harvestable surpluses for treaty and non-treaty fisheries. The DEIS lacks survival, recovery and delisting goals specific to the listed and non-listed anadromous fish populations considered under the alternatives.

[2] NMFS has allowed Douglas and Chelan PUD to proceed with Phase I of the HCP under a "conditional HCP implementation policy," over strong tribal objections. Given that environmental review is not completed, an HCP Agreement remains unsigned, and a Section 10 Permit has been issued the legality of this action is highly questionable. However, Chelan is proceeding to finalize installation of a major bypass system that will likely exacerbate the decline of Pacific lamprey and sensitive salmon stocks which are Plan Species but not ESA- listed species.

11

- The DEIS fails to describe how the various alternatives relate to other applicable treaties and laws, including tribal treaties, the Clean Water Act and the *U.S.- Canada Pacific Salmon Treaty.*

12

- The DEIS failed to determine whether the 7% hatchery component can actually be achieved with or without Grant PUD's involvement in the HCP. Further, it remains unresolved in the DEIS how "no net impact" (NNI) would be accomplished if NMFS deems the 7% hatchery component unfeasible because of particular genetic or policy concerns with respect to supplementation. This is a key failing of the DEIS.

General Comments

13 There are many incorrect statements and factually erroneous declarations in the DEIS. While the following comments will serve to highlight some of the inaccuracies, we will not address them all. As stated above, most of the scoping issues identified by CRITFC were never addressed in the DEIS. For these reasons, the DEIS is a fatally flawed document and should be completely rescoped and reanalyzed.

14 The document abstract states that the HCPs satisfy the PUDs' regulatory obligations under the Federal Power Act. This is not factually correct. Future relicensings, measures to protect species not addressed by the HCPs and treaty obligations under tribal treaties and the *U.S.-Canada Pacific Salmon Treaty* are all

15 obligations that must be satisfied whether or not an HCP is consummated. Further, the HCPs will not satisfy standards under the Clean Water Act.

16 In the summary section it states that, "the parties have been engaged in cooperative HCP planning for over 6 years." This is not correct. Tribal parties have been in dispute with NMFS and the PUDs for much of that time, and are not in agreement with the proposed HCP documents at this time. Details of these disputes are provided below.

On page S-3 it is stated that, "the effects of Rocky Reach, Wells and Rock Island on anadromous fish *may* continue downstream through the Hanford Reach to McNary Dam." [emphasis added]. The Joint Fisheries Parties agree that the effects will continue downstream, whether they are from dissolved gas generated from the HCP projects, or injuries suffered when passing through these projects.

17 On page S-18 it is stated that the NNI standard of 95% survival per dam was developed in coordination with tribal biologists. However, not all tribal biologists agreed with the standard. The DEIS states that the NNI standard of 95% survival is consistent with the 1995 FCRPS Biological Opinion. While this is factually correct, it leaves out the other major criteria for passage systems required by the 1995 FCRPS, such as an 80% Fish Passage Efficiency (FPE) standard.[3] Because tribal biologists desired that the NNI

[3] Fish Passage Efficiency (FPE), as defined by the 1995 FCRPS Biological Opinion at VIII. 15, refers to the percentage of the juvenile migration that passes over a dam through non-turbine routes. The tribes have

standard would be consistent with the three basin restoration plans,[4] tribal biologists strongly recommended that the NNI standard have dual and complementing components, 95% survival and 80% FPE. This recommendation was rejected by NMFS and the PUDs.

18

Since the signing of the Commemorative Declaration of the HCP on June 27, 1998, the NMFS, Chelan PUD, Douglas PUD, WDFW and USFWS have been under a false assumption that the HCP was established, and that it should be under "conditional implementation"until the environmental review is completed and the Section 10 Incidental Take Statement finalized. The PUDs have embarked upon survival studies to determine HCP NNI standards without agreement from the Joint Fisheries Parties as to methodologies, principles and results. Chelan PUD recently unilaterally declared that they have reached the NNI standard of 95 % at both Rock Island and Rocky Reach dams, and that reduced spill at Rock Island and complete reliance on the Rocky Reach prototype bypass system are appropriate to protect listed and unlisted anadromous fish as they pass these dams (Attachment 2). Several of the Joint Fisheries Parties strongly object to Chelan's unilateral decisions under "conditional implementation" of the HCP as a proxy to reduce critical fish protection measures (Attachments 3,4,5,6,7).

These actions indicate extreme bad faith on the part of Chelan PUD in resolving key issues that remain unaddressed in the DEIS. The acceptance of "conditional implementation" by the non-tribal parties involved in the HCP negotiations has, in effect, stymied important progress in resolving key relicensing issues for the Rocky Reach Project (Attachment 7). The DEIS has not addressed these issues, which are critical to the future of the fisheries resource, because of the very depressed status of listed and unlisted Mid-Columbia anadromous fish stocks (TAC 1997; Cooney et al. 2000). The final EIS should address these issues.

Environmental Baseline

19

The DEIS defines the environmental baseline as the status of the anadromous fish stocks and their critical habitat in the 1970's when they were already depressed and degraded. This is inconsistent with the NMFS' 1995-8 FCRPS Biological Opinion (at page 12) that defines the baseline as the effects of the proposed action that would be added to the past and present impacts of all Federal, State, and private activities in the

---

defined FPE as the percentage of the juvenile migration that passes over a dam through spill or surface bypass, and they, as NMFS, have adopted the dual criteria in their Columbia Basin salmon recovery plan, *Wy-Kan-Ush-Mi Wa-Kish-Wit* (Nez Perce et al. 1995). Adoption of the FPE standard is critical because it provides a measurable standard that covers the entire migration, rather than just a snapshot of survival provided by survival studies. An FPE standard also incorporates the available scientific literature that reviews comparative survival studies through different passage routes. This includes scientific information about delayed mortality and smolt-to-adult returns. These attributes cannot be assessed by limiting passage criteria to a simple measurement of survival for a distinct group of salmon through a dam over an extremely limited range of environmental conditions. Thus, the NNI standard lacks consistency and lacks a true assessment of the impacts of the Projects on the anadromous fish resource.

[4] The three plans are the 1995-1998 FCRPS Biological Opinion, the CRITFC tribes' 1995 restoration plan *Wy-Kan-Ush-Mi Wa-Kish-Wit*, and the Northwest Power Planning Council's 1994 *Strategy for Salmon*.

action area. The action area is defined as, "all areas to be affected directly or indirectly by the federal action and not merely the immediate area involved in the action."

Critical Habitat

20 The DEIS fails to address listed species critical habitat. This is inconsistent with the 1995 FCRPS Biological Opinion (IV p. 82) which defines critical habitat as that which is critical to the survival and recovery of the species and determines whether or not the proposed operation adversely modifies or destroys the listed salmon's critical habitat.

Specific Comments

S.5 No Action Alternative

21 The No Action alternative, with extant baseline conditions and no action, is not an authentic alternative. Because upper Columbia spring chinook and steelhead are ESA listed, ESA Section 7 consultation and Section 10 Incidental Take permits must be conducted. In the case of the Wells Project, these have been consummated. NMFS, however, has failed to finalize these consultations for the Rocky Reach or Rock Island projects. Thus, this alternative is premature until these consultations are finalized and appropriate permits and biological opinions have been issued. It should be deleted from the final EIS unless these opinions and permits are finalized.

22 The DEIS fails to mention that the Rocky Reach prototype juvenile bypass system has been under dispute from tribal parties since it was first conceived. The Fourth Interim Stipulation for the Rocky Reach Project required Chelan PUD to seek consensus in developing the system. However, conditional implementation of the HCP has allowed Chelan to proceed with development of the system while it is still under dispute (Attachment 7). Thus, Alternative 3 (the HCP) has significantly impacted the other two alternatives. The final EIS must clarify these issues when defining the alternatives.

Currently Chelan PUD is refusing to honor the Fourth Interim Stipulation for Rocky Reach, which requires spill to 15% daily average flow. This situation also impacts the definition of Alternative 1, in that Alternative 1 as described is not reality. Further, the DEIS is incorrect when it states that the "main goal" of the Fourth Interim Stipulation was to build a bypass system. From the Joint Fisheries Parties'perspective, the main goal of the stipulation was to obtain immediate fish protection through spill, and advance mitigation and compensation for losses through the Rocky Reach Project.

23 With respect to Rock Island, the Alternative 1 in the DEIS does not accurately describe the baseline condition. A spill agreement between NMFS and Chelan, under the "conditional implementation" of the HCP, removed the spill authority from the other Joint Fishery Parties and the spill conservation account management specified under the Rock Island Settlement Agreement (Attachments 7 and 8).

S 5.2 Alternative 2 (Section 7 Consultation)

24 The DEIS fails to mention that the QAR report indicated a substantial risk of extinction for Mid-Columbia River spring-run salmon and steelhead if recent survival rates continue without supplementation. The final EIS must correct this oversight. Further, if the Mid-Columbia dams were removed, then recent total life-history survival rates would not continue, because survival, fish critical habitat and productivity would dramatically increase through the Mid-Columbia reach.

25 No rationale is offered why a screened bypass system would be included at each dam for Alternative 2. If spill is sufficient enough to meet downstream passage objectives, then it would stand alone.

26 If studies show that drawdown and decommissioning (dam removal) are necessary to meet recovery standards that provide harvestable surpluses, then these options would proceed under a relicensing process. No rationale is given as to why the decision would be postponed, given the high probability that upper Columbia listed species, closest to extinction in the basin, may expire in the near future without such measures.

27 The DEIS is inconsistent with the 1995-1998 FCRPS Biological Opinion and completely speculative as to the benefits that could be derived from minimum operating pools at the Mid-Columbia Projects. Drawdowns to minimum operating pool have been a fundamental reasonable and prudent measure under the 1995 FCRPS Biological Opinion, and haven't been studied at the Mid-Columbia projects.

28 A major strength of Alternative 2 is that there are many avenues to create and prescribe measures that are necessary for recovery of listed salmon by fishery experts who have the legal and management authorities to protect the resource, and the statutory authorities of the federal agencies are fully maintained. For example, actions through relicensings, actions through the Mid-Columbia Proceedings, actions under the ESA and actions under the Clean Water Act are all possible remedies to promote and achieve meaningful recovery measures. The final EIS should fully describe these attributes associated with Alternative 2, but not available under Alternative 3.

S. 5.3.1 Alternative 3 (Project HCPs)

29 The HCPs fail to include Pacific Lamprey, sturgeon, and ESA listed bull trout. Whether or not these would be afforded protection would be up to other processes, including the Federal Power Act and the Northwest Power Act. This is a key deficiency of the HCP.

30 Full mitigation has not been provided for anadromous fish losses at the HCP projects. From a tribal perspective this includes both listed and unlisted species. Currently, Rocky Reach and Rock Island are illegally taking listed salmon without a Section 7 Biological Opinion under the "conditional implementation" of the HCP as

allowed by NMFS. This demonstrates that under a consummated HCP, listed species would continue to be taken and driven to extinction.

31 Existing hatcheries have not provided adequate compensation for the initial construction of dam and reservoirs and the continual passage losses through the dams. NMFS' supplementation policies that restrict hatchery compensation add additional blockages to full mitigation and compensation.

32 The environmental baseline should consist of pre-project river conditions and population levels of anadromous salmon, or just prior to 1933 when Rock Island was constructed. No rationale is given in the DEIS to explain why the baseline conditions are moved from 1933 to 1977.

33 The terms of the HCP are arbitrary and not biologically based. Each PUD is given from 15-20 years to achieve NNI. Given the current status of the upper Columbia stocks presented in the QAR (Cooney et al. 2000), it is very likely that these stocks will be extinct by the time that the PUDs achieve NNI. Under the HCP alternative, if a stock is headed toward extinction, neither NMFS nor the other fishery parties have leverage to force operational or structural changes to improve passage at PUD projects.

34 NMFS and the USFWS would not withdraw from the HCP if the PUDs met all conditions except the performance standards, which are the heart of the HCP. Thus, the federal agencies with jurisdiction over the ESA would not have the leverage of the ESA to prevent extinctions. Further, NMFS and USFWS are restricted from recommending drawdowns and/or project removal without the consent of the PUDs- effectively removing a key restoration action that may be required to prevent extinctions.

S.5.3.4 HCP Mitigation Objectives

35 The HCP alternative includes measures from a biological standpoint, but not a physical and chemical standpoint. Biological measures and criteria stem from physical and chemical measures. For example, if temperature, a physical parameter, is too warm, then salmonids develop biological responses such as stress, disease and mortality. This is a significant omission in the HCP alternative.

36 As previously mentioned, the effects of the projects on anadromous fish go well beyond 1,000 feet below an individual project. This was an issue raised by tribal biologists but disregarded by NMFS and the PUDs. Water quality parameters such as dissolved gas, can directly and cumulatively impact stocks below a project. These impacts include stress or injury of fish as they pass the project that result in direct and delayed mortality by predators or disease well after the fish have passed an individual project. This is another concern with Alternative 3.

S.5.3.5 HCP Performance Standards

37 The original intent of the NNI standard was to make the dams, "transparent." However, the standards were developed without any quantitative analysis. Further, the standards remain speculative because the PUDs have not obligated themselves to fund measures that will contribute to meeting the standards (ie; spill at dams, habitat improvements and full supplementation production) and the measures themselves remain very speculative. For example, NMFS will not guarantee the 7% hatchery component, because of policy concerns related to genetic management, thus, it is impossible for the NNI standard to be achieved. It is disingenuous and factually wrong for NMFS to characterize Alterative 3 in the DEIS as consistent with the proposed HCPs that guarantee the 7% hatchery component.

38 The habitat component of 2% is purely speculative. It remains unknown whether or not this is obtainable. Specific measures that should be implemented to attempt to achieve this piece of the NNI standard remain unresolved.

39 The 95% and 91% dam and project survival standards, as noted by tribal biologists during the HCP discussions, are not sufficient to foster recovery of severely depressed salmons stocks, particularly to havestable levels. These standards must be viewed from a cumulative, exponential perspective, rather than a linear perspective. From an exponential perspective, the 95% dam survival standard results in (.95) raised to the third power or 85.7% survival through three dams. Likewise, a 91% project survival standard results in only a 75.4 % survival through three hydroprojects. These losses are much too great to sustain, much less recover upper Columbia stocks. Due to the extreme depressed status of the runs and the desire of tribes for recovery of treaty resources, some tribal biologists sought a 98 % survival standard during the HCP discussions.[5] If achieved, this standard would have resulted in a 94.1 % survival rate through three projects or dams.

40 A major omission of Alternative 3 in the DEIS is the failure to include passage and survival standards for adult anadromous fish. This was a contentious issue in HCP negotiations for some tribal biologists. While some adult losses were calculated into the compensation numbers, the lack of measurable adult passage standards allows the PUDs to avoid operational or structural measures necessary to improve adult passage and survival through the projects. Given that one successfully spawning adult can contribute 3,000-5,000 eggs to the next generation, CRITFC has recommended adult passage standards requiring mainstem dam operators to decrease pre-spawning mortality due to dam passage and passage time through their projects by at least 50% (CRITFC 2000). The 2000 FCRPS Biological Opinion at least requires reduction of adult fallback as a means to increase adult passage survival. The HCP alternative fails to provide any standards. Further, power peaking, an action that has been shown to reduce adult passage success (Bjornn and Peery 1992) is not addressed in the DEIS.

[5] During the relicensing process for the Lower Elwha and Glines Canyon dams, tribal, state and federal biologists determined that a 98% juvenile survival standard was necessary to restore five races of anadromous salmon and steelhead to the Elwha River.

S.5.3.6 HCP Phases

41 Because the HCP is already under "conditional implementation," steady progress toward achieving the survival standards should be required. However, the exact meaning of "steady progress" was never defined or quantified by the parties. It is clear that Chelan PUD is failing to make steady progress at both Rock Island and Rocky Reach since juvenile fish guidance decreased in 2000 from 1999 levels (Murphy et al. 2000); in 2001 Chelan ended Rocky Reach spill which in 2000 was 15% of daily average flow and Chelan has reduced 2001 spill from 2000 spill levels at Rock Island (Attachment 8). This raises the question as to the meaning of "steady progress."

42 While in theory it might be appropriate for the PUDs to move on to Phase III if performance standards were met for some species, in reality there may be other species that migrate at the same time that are not achieving the standards. These species may be subjected to passage "tools" that benefit other species but select against the species that have not met the standard. Thus, they are not protected.

43 The Mid-Columbia Coordinating Committee has yet to resolve issues related to the performance standards. There remains serious disagreements about the tools and methodologies to measure the standards, appropriate ranges of flow years to consider, life cycle analyses, delayed mortality and other issues. Under the existing Mid-Columbia settlement agreements and the Mid-Columbia proceedings, the coordinating committees operate under a consensus basis. This would be altered under Alternative 3. Under Alternative 3, the HCP coordinating committee would no longer be ruled by consensus. Instead, the PUDs would have the final decision on what passage tools to use, even in Phase III after NNI and/or the performance standards are not met. This represents a significant loss of authority for the tribes and other members of the Joint Fisheries Parties and is unacceptable.

Wells Dam

44 Section E. 2 of the existing 1990 Wells Settlement Agreement requires Douglas PUD to provide juvenile salmon with an 80% and 70% fish passage efficiency protection over the entire migration (100% of the migration). The Alternative 3 performance standard reduces juvenile protection to the middle 95% of the spring and summer migrations. The lack of protection on the beginning and end of the migration selects against important genetic and life history characteristics of the population and works against overall stock recovery.

Rocky Reach Dam

45 As previously stated, limiting performance standards to point estimates of survival for one group of fish for one environmental condition fails to consider the impacts of hydroproject passage for an entire stock over a number of varied environmental conditions. Further, survival study methodologies employed by the PUD

are in dispute with some of the JFP. In particular, critical assumptions that are necessary to make survival estimates robust continue to be violated.[6]

As Chelan PUD refuses to spill at Rocky Reach for the 2001 migration under the conditional implementation of the HCP, there is no assurance that spill would continue to
46 be provided under Alternative 3 (Attachment 8).

Rock Island Dam

As Chelan PUD has significantly reduced spill at Rocky Reach for the 2001 migration under the "conditional implementation" of the HCP despite entreaties from NMFS (Attachment 6), there is no assurance that spill would be provided under Alternative 3.

Tributary Conservation Plan

47 In the original HCP discussions, about $100 million was deemed necessary by the JFP to achieve a 2% habitat improvement component to NNI. The DEIS states that the PUDs would contribute less than $ 4 million to the habitat fund. This is less that 4% of the original estimate and would fail to achieve the 2% component of the NNI goal.

Hatchery Compensation Plan

48 Alternative 3 would not afford coho the same standards for compensation as the other plan species. It is unclear why this is the case. In Alternative 2, coho would be afforded mitigation and compensation.

S.5.3.9 Provisions for Impacts on other Species

49 It is very likely that the turbine intake screen system at Rocky Reach Dam, installed under "conditional implementation" of the Alternative 3, will likely impinge juvenile lamprey as been seen at Corps' mainstem dam screen systems (NWPPC 1999). Based upon information at Corps dams, the Rocky Reach bypass system will likely injury bull trout, an ESA listed species, because the system passage will cause physical injure similar to that experienced by adult salmon and steelhead. Wagner and Hilson (1991) found 41% of the adult steelhead that fell back through the McNary Dam screen system had visible bruises.

[6] Current survival studies implemented by the PUDs employ mark and recapture techniques that compare downstream passage detection of a group of fish above one dam to those released below the dam. If the fish from both groups fail to experience identical passage conditions downstream, then a key critical assumption necessary to validate the survival estimate is not met. The model assumes that similar arrival times of marked groups to downstream detection sites satisfies the assumption of identical passage conditions. However, Chi-Square Goodness-of-Fit analyses indicate that the groups do not necessarily arrive at the same time, thus, making suspect survival estimates.

S.3.5.14 Clarification of Issues

While Douglas PUD has conducted survival studies, whether or not the 91% project survival parameter has been met is still under dispute. Douglas has yet to conduct a study that evaluates yearling juvenile survival through the entire Wells Pool, nor have they conducted survival studies for subyearling salmon or sockeye.

Verification of Standards

50 No specific biological or statistical standards have been agreed to by the JFP. Representative tools are not available to measure performance standards for all of the planned species. The DEIS appears to indicate that dam passage survival would be the only measurement available to measure the performance standard. Yet the HCP requires survival measurements of the entire project. The DEIS appears to modify the intent of the draft HCP agreements, similar to the modification of the 7% hatchery component.

S.7.2.2 Alternative 2

51 The DEIS fails to mention that Alternative 2 would require NMFS to consult with affected tribes under the Secretarial Order. The DEIS also fails to mention that under Alternative 2, NMFS and the Department of Interior maintain their authorities under the Federal Power Act to condition the dams for fish passage and even condition the dams for project removal.

S.7.2.3 Alternative 3

52 Under Alternative 3, the burden of proof is on the party bringing an issue to dispute resolution. Because Alternative 3 establishes the JFP with the burden of proof, the JFP have the burden of demonstrating that their position (to protect and restore the resource) is accepted by a third party. This is a key drawback of Alternative 3 for the JFP. In Alternative 2 the burden of proof is equally placed between the PUDs and the JFP.

53 The "no surprises policy" guarantees that the PUDs will not have to take additional measures to assure recovery of the resource in the 50 year HCP period. The tribes have no such assurance for the health and abundance of the resource or that their harvest rate will be protected.

These aspects of Alternative 3 are unacceptable to CRITFC.

S.7.4.3 Alternative 3

54 As noted above, Alternative 3 as defined in this DEIS fails to guarantee 100% NNI. Neither the hatchery component nor the habitat component is assured.

Adaptive Management

55 Adaptive management, as defined by Hilborn (1987) means that experimental, probing actions are implemented, monitored and evaluated. Based upon the results, more actions are taken. In the true sense of adaptive management, all passage solutions would be used as probing experiments, including drawdowns. Under the HCP, drawdowns are not jointly considered. Thus, Alternative 2, which allows a range of probing actions, is more likely to achieve an adaptive management context than Alternative 3.

S.7.6.2 Alternative 2

56 Under Alternative 2, provisions of the Clean Water Act, the Federal Power Act, the Northwest Power Planning Act, tribal treaties and other laws and statutes are available to protect and restore Mid-Columbia anadromous fish through increased operational and structural measures and supplementation.

S.7.5.3 Alternative 3

57 Under the HCP, as noted above, Alternative 3 as defined in the DEIS fails to guarantee 100% NNI. Neither the hatchery component nor the habitat component are assured.

S.7.6 Other Environmental Measures (Table S-3)

The DEIS is incorrect or fails to express the following in the environmental comparisons and in general lacks analysis of alternatives from an ecosystem approach as noted by Williams et al. (1996) and Lichatowich and Mobrand (1995):

58 Project area soils- only Alternative 2 provides drawdown or project removal options. Riparian areas would be restored increasing mainstem spawning, incubation and rearing habitats through restoration of lotic properties instead of reservoir/lentic properties (Williams et al. 1996).

59 Reservoir erosion and sedimentation- only Alternative 2 provides drawdown or project removal options. These would reestablish natural river sediment transport regimes in the project area contributing to increased anadromous fish production (Vannote et al. 1980). For example, increases in turbidity would provide cover for juvenile salmon from predators and increase production as noted by Junge and Oakley (1966) and NMFS (2000).

60 Tributary Channel and watershed conditions- only Alternative 2 provides drawdown or project removal options. This would restore vital habitat linkages between tributary and mainstem areas. In particular, summer chinook habitat at the confluence between the tributaries and the mainstem would be restored (Williams et al. 1996).

61 Juvenile Migration/Survival standards- only Alternative 2 has the stated goal to require standards necessary to recover listed species, while leaving flexibility to establish standards through other laws and statutes necessary to recover unlisted species.

62 Adult Migration/Survival standards- only Alternative 2 has the stated goal to require standards necessary to recover listed species, while leaving flexibility to establish standards through other laws and statutes necessary to recover unlisted species. Alternative 3 has no adult standards.

63 Drawdown- as stated above, drawdown will increase fish spawning and rearing habitat and adult and juvenile survival, for a cumulative net production benefit. Winter (1990) gives several examples of anadromous fish restoration through dam removal. These issues are not mentioned, yet they are significant.

64 Bull trout- Alternative 2 allows the USFWS to engage in Section 7 ESA consultations and through the Federal Power Act, condition the projects to protect and restore bull trout. Alternative 3 does not allow this conditioning since bull trout are not an HCP species.

65 QAR results- the DEIS fails to consider that drawdowns or project removals would increase survival and significantly increase productivity through habitat restoration. The QAR did not consider the benefits to habitat restoration. As stated in the table, the effects of supplementation have not been analyzed in the QAR. This is a key deficiency in the DEIS that should be addressed. The statement that "*habitat productivity*" would increase survival under Alternative 3 from 6-10% is completely speculative and not supported by any DEIS analysis.

66 Fisheries resources- this section is not consistent with other parts of the DEIS. For example, under Alternative 3, coho are not afforded immediate supplementation, but the table indicates that they are afforded supplementation. Under Alternative 3, the retention of reservoirs will continue to provide excellent habitat for fish predators on salmon as compared to restoring lotic conditions possible under Alternative 2.

67 Monitoring- under Alternative 2, NMFS and the JFP could condition the licenses and appeal to the Clean Water Act provisions to provide both fish and water quality monitoring. Under Alternative 3, the JFP have no authority to obtain fish and water quality monitoring at the projects.

68 Total Dissolved Gas (TDG)- under Alternative 2 the JFP could condition the licenses and appeal to the Clean Water Act provisions to provide for reductions in total dissolved gas by either drawdowns or project removals that would limit deep plunging and entrainment of nitrogen. These provisions could also force the PUDs to install structural modifications to the dams to reduce TDG. Under Alternative 3, the JFP have no authority to regulate the PUDs to reduce total dissolved gas. Downstream reductions of total dissolved gas would be possible under Alternative 2, which would increase fish survival at lower river dams through increased spill at these dams and decreased risk of

gas bubble trauma from reduced exposure to elevated gas. This is a cumulative benefit that the DEIS failed to fully analyze.

Temperatures- The DEIS failed to address this critical parameter. Data from Jaske and Gobel (1957) and more recent data (Corps 2001) indicates that the projects contribute to violations of temperature standards. Under Alternative 2, the JFP could
69 condition the licenses and appeal to the Clean Water Act provisions to provide both fish and water quality monitoring. Under Alternative 3, the JFP have no authority to obtain fish and water quality monitoring at the projects.

Wildlife- the DEIS fails to mention that under Alternative 2, draw downs and
70 project removal would restore anadromous fish and riparian wildlife habitat. These would also contribute to the restoration and enhancement of wildlife populations. Alternative 3 would not restore riparian wildlife habitat, thus, depression of wildlife populations would persist.

Economics – Alternative 2 would allow for restoration of natural resources through draw downs, project removal, or appropriate passage conditions. These would promote natural river recreational opportunities that are at least equal or greater than that
71 provided by retaining the projects and reservoirs. Increased sport, tribal and commercial fishing activities would be available from restoration of natural resources, yet the DEIS does not address these. As note below, tribal health, welfare and socio-economics could be vastly impacted by the alternatives, yet the DEIS fails to address these issues.

72 Cultural resources- the DEIS fails to address the anadromous fish resource as a critical cultural resource. The projects occupy ceded lands of the Yakama Nation. Maintaining the status quo or limiting restoration under Alternatives 1 and 3 will continue to impact tribal cultural resources.

1.5.2.6 Federal Trust Responsibilities to Indian Tribes

73 The DEIS fails to distinguish the differences between trust responsibilities and treaty protection. The courts in United States v. Oregon have stated that all non-tribal conservation measures must be exhausted before the treaty tribes right to harvest is diminished. Alternative 3 with a "no surprises" policy allows the PUDs to limit their efforts to harvest salmon through their hydroprojects, effectively shifting the conservation burden back to the tribes. This is not consistent with the law and equitable sharing of the conservation burden.

74 The DEIS should state that the tribes will not endorse the HCPs if NMFS will not guarantee the 7% hatchery compensation necessary to achieve NNI.

1.6.3 Alternative 3

75 The footnote on page 1-16 contains contradictory statements. The proposed draft HCP agreements commit to the 7% hatchery component for NNI, yet in the DEIS, NMFS

cannot commit to the 7% hatchery component. Yet, the footnote says that NMFS is committed to the proposed draft HCPs. NMFS can't have it both ways.

76 Since the "conditional implementation" of the HCPs has been implemented, juvenile salmon protection has already been unilaterally diminished by Chelan PUD at Rocky Reach and Rock Island dams. In April, 2001, Chelan reduced Rock Island spring spill from 31 kcfs to 20% of daily average flows and completely ended Rocky Reach spill. This indicates clearly that Alternative 3 would not meet the requirements of the treaties, ESA, the Federal Power Act and the Northwest Power Act.

77 p. 1-25 The CRITFC tribes restoration plan, *Wy-Kan-Ush-Mi Wa-Kish-Wit* has specific recommendations for the hydroprojects and watershed area under consideration yet it is not mentioned in the DEIS.

p. 2-10-2-15

78 The DEIS fails to mention that recent estimates for turbine mortality in the DEIS occurred during high flow years with good water conditions. Estimates have yet to be established for poor water years, yet need to be. Further, the DEIS uses Snake River turbine estimates for Wells, Rocky Reach and Rock Island, when there are specific turbine mortality data for these projects. For example, steelhead mortality through turbines at Wells Dam is cited as 16% while Rock Island turbine mortality was cited as 5.7% or 13% (Whitney et al. 1997). The DEIS should have cited specific data that is available for specific projects.

79 Adult median passage times through fishways is a nebulous statistic. What is more important is the range of outliers in the data set. For example, according to adult passage studies, it can take days and even weeks for some salmon to pass these dams. Such delays compromise adult spawning success and distribution into more favorable spawning areas and waste precious energy reserves.

80 As stated previously, there are problems with the robustness of the estimates of survival using the mark and recapture pit-tag survival studies. At best, they are a snapshot of the survival of a particular group of marked fish and do not adequately represent survival of even one years' migration. Alternative 3 limits accounting of juvenile salmon protection to these snapshots while failing to incorporate passage standards for the migrations as a whole.

81 Juvenile mortality through screen bypass systems is much higher than indicated in the DEIS. For example, subyearling chinook direct and indirect mortality at the Bonneville Dam second powerhouse screen bypass system was documented at 20% (Gilbreath et al. 1993). Matthews 1987 (in Chapman and Witty 1994) notes that yearling chinook suffered an average of 5.8% mortality from the Lower Granite bypass system. In 1977, al low flow year, juvenile mortality in bypass systems was as high as 30% (Park et al. 1978). IDFG (1998) and Deriso et al. (1996) reported that adult returns trended negatively from juvenile pit-tagged salmon that went through multiple bypass systems.

82 Screen systemsalso negatively impact sockeye causing large rates of descaling and impinge juvenile Pacific Lamprey. The DEIS should be modified to include all relevant studies on the impact of these systems on salmon.

83 The DEIS speculates that the Rocky Reach bypass system can achieve a 98% survival rate, without any supporting data. Guidance for migrants in 2000 significantly decreased in 2000, which the DEIS fails to mention. Based upon pit-tag detection guidance for sockeye and subyearling chinook was only 7% and 27% respectively (Murphy et al. 2001). These extremely low guidance rates indicate that spill should be increased. Instead, Chelan PUD, under NMFS' definition of conditional implementation of the HCP, has completely shut off spill (Attachment 8).

84 Under controlled spill conditions, total dissolved gas has not been shown to impact salmon survival (Backman et al. in press; Backman et al 2000). The DEIS fails to examine the wealth of literature available that indicates the extreme risk to salmon populations from not spilling and sending salmon through bypass systems or turbines.

p. 2-16-2-17

85 The DEIS states that adult survival estimates have not been established for the Mid-Columbia. This is incorrect. NMFS and the Idaho Cooperative Fishery Unit presented adult survival data for Mid-Columbia spring chinook and sockeye (Bjornn and Keefer 1999). Survival from Rock Island to Wells Dam for spring chinook is about 91% and for sockeye is about 97%.

p. 2-18

86 The DEIS fails to include NMFS' conclusion in the 1998 Supplemental FCRPS Biological Opinion that there is a strong relationship between flow and reduced travel time for juvenile steelhead. This led NMFS to adopt a target flow in the Mid-Columbia of 135 kcfs for spring migrants. Other supporting literature that indicates reduced travel time for juvenile migrants is related to flow includes Cada et al. (1994) and Williams et al. (1996). Reduction of smolt travel time is positively related to increased smolt-to-adult returns as noted by Petrosky and Schaller (1998) and Schaller et al.(1999) and DeHart (1999). Alternative 3 does not include drawdowns that would decrease smolt travel time to the estuary. The DEIS should be modified to include a holistic assessment of the benefits of increased flows and reduced travel time to salmon production.

2.2.4.1 Water Quality

87 Due to forced spill, the projects can cause total dissolved gas levels to exceed Clean Water Act Standards. Under "conditional implementation" of the HCP, the PUDs are doing little to establish structural remedies to bring the dams into compliance with the standards. The DEIS should be modified to reflect these issues.

88 The loss of turbidity from the existence of the projects has also diminished salmon productivity as noted by NMFS (1999), CRITFC (1999) and Junge and Oakley (1966). The alternatives should be analyzed from this perspective.

2.2.4.2 Water Temperature

89 The creation of the Wells, Rocky Reach and Rock Island Dams has altered thermal regimes in the Mid-Columbia River as noted by Jaske and Gobel (1967) and has at times created thermal blocks for salmon migrations (Major and Mighell 1966). Water temperatures at these dams and passage facilities often exceed water quality standards (DART 1997-2000) for a considerable portion of the summer. Under "conditional implementation" of the HCP, the PUDs are doing little to establish structural remedies to bring the dams into compliance with the standards. Cooler water at depth could be used to regulate thermal regimes in fishways. The DEIS should be modified to reflect this issue.

2.3.3.11 Project Cumulative Effects

90 The DEIS fails to consider cumulative effects from a reach-based perspective. This is inconsistent with the FERC approach for the upper Snake River. In 1997, FERC initiated a cumulative effects analysis through an EIS for the entire upper Snake River reach.

91 The DEIS is also inconsistent with the NMFS cumulative effects approach for the federal hydrosystem. The NMFS 1995-1998 FCRPS Biological Opinion states, under Section V Cumulative Effects (p82) that, "for the purposes of thie analysis, the action area encompasses the Snake and Columbia Rivers, including areas outside the range of listed Snake River salmon that affect natural runoff of water into those areas that are within the listed species' range". Thus, the HCP should include projects and areas above the Wells Project.

p. 3-156 3.9.3.3

92 The DEIS statement that a 1969 Supreme Court decision in *U.S. v. Oregon* established the right to fish at all usual and accustomed areas is incorrect. There was no 1969 decision. The Supreme Court established that the 1855 treaties reserved the rights of the CRITFC tribes to fish as found in *United States v. Winans*. Federal District courts in Washington and Oregon have defined the tribes' rights to fish on and off the reservations in Sohappy v. Smith and U.S. v. Washington. The DEIS sentence that reads,"the court later decided that the Columbia River Tribes were entitled to should be changed to", "The court has decided that..".

4.7 Socioeconomics

93 The DEIS fails to include an analysis of the socioeconomic impacts of the alternatives on tribal economies. Most of the salmon wealth has been taken away from

the tribes and redistributed to non-tribal people in the form of flood control, navigation, irrigation and municipal development. This redistribution of wealth from tribal people that originated in the Mid-Columbia region has resulted in elevated poverty and death rates within tribal populations well in excess of the general population (Ch2 M Hill 1999). In particular, the loss of salmon from construction and operation of the Mid-Columbia PUD hydroprojects has transferred the sustainable wealth created by the river away from tribal peoples and has redistributed this wealth to non-tribal peoples (CH2 M Hill 1999). For example, the Yakama Nation tribal members have access to and take less than 10% of their traditional salmon harvest.

Loss of tribal wealth and the diminishment of opportunities to exercise treaty fishing rights from the depletion of salmon stocks has resulted in disproportionate rates of poverty, disease, mental illness and death in tribal communities compared to non-tribal communities (CH2 M Hill 1999). For example, the per capital income of a Yakama Nation tribal member is only 43% of the State of Washington per capita income, and the poverty rate of a Yakama Nation tribal member is 42.8% compared to the average citizen of Washington State at 10.9 % (CH 2 M Hill 1999).

Further, salmon are the mainstay of tribal religious and cultural practices. Every juvenile salmon that survives hydrosystem passage brings back as an adult some of the river's wealth to the tribal economy and culture. The DEIS alternatives must be evaluated as to their effects on tribal culture and economies and the alternatives ability to redistribute the river wealth back to tribal peoples.

4.10.7 Indian Trust Assets

94

While the guarantee of the 7% hatchery component is an important issue for the tribes, there are other important issues, including the inadequacy and lack of definition for the Alternative 3 performance standards, the "no surprises" policy, and the loss of JFP authorities under various laws and statutes.

The DEIS is incorrect when it states that, "the 7% level is similar to the existing hatchery production under the FERC settlement agreements." The current Wells Settlement agreement provides for a 14% hatchery production level for unavoidable juvenile losses through the Wells Project. Further, the DEIS is incorrect in stating, " meeting the 7 percent annual goal would guarantee a hatchery production level that supports current tribal harvests and ensures the Tribes that hatchery production would not decline." Current tribal harvest objective on upper Columbia anadromous fish stocks are not being met with current hatchery production (Nez Perce et al. 1995).

The courts in *United States v. Washington* have fully supported the tribal position that hatchery fish are treaty trust resources. The final EIS should clarify this issue. Lastly, the DEIS is erroneous in stating that the settlement agreement numbers were for fish losses from original dam construction. Both the Rock Island and Wells Settlement Agreements have mitigation components that require hatchery compensation for juvenile salmon passage losses.

4.10.8 Environmental Justice

95 Both Alternatives 2 and 3 will impact tribal economies that rely upon the health and abundance of treaty anadromous fish in different ways. Alternative 2 will allow retention of federal authorities and protection of treaty resources from a variety of different statues and laws. Alternative 3 will cause federal trustees to essentially dismiss their authorities for a 50 year period. The DEIS is incorrect in stating that Executive Order No. 12898 is not relevant to the DEIS alternatives. The final EIS should provide analysis of the alternatives in relationship to the Executive Order.

4.10.13 Water Rights

96 The implementation of each alternative will impact tribal and non-tribal water rights in different ways. For example, in a low flow year water withdrawals from the Columbia Basin can diminish mainstem flows to the point where spill is jeopardized at the PUD hydroprojects. Further, spill at dams is a water right in that it is the use of water for fish instead of for power. The final EIS needs to analyze the issue of water rights from the perspective of the alternatives.

Summary

The DEIS fails to address fundamental issues raised in CRITFC's scoping comments. In addition, the DEIS contains many erroneous statements and fails to provide analyses for critical issues such as the impact of alternatives on tribal socioeconomics and tribal trust assets. The DEIS is further flawed because it fails to reconcile the fact that NNI is dependent on the 7% hatchery component as called for by the proposed HCPs, while NMFS' position and the DEIS state that the HCPs are "whole" without the 7% hatchery component.

The DEIS fails to analyze the alternatives from an ecosystem perspective and a water quality perspective. The DEIS cumulative and quantitative effects analysis is lacking, and the environmental baseline begins in 1977, which is nearly 50 years after the construction of the Rock Island Project. Further, the DEIS fails to analyze the effects of the alternatives on returning adults to natal spawning areas. The DEIS should be completely rescoped and redone if parties continue to support an HCP concept.

97 The acceptance of "conditional implementation" by the non-tribal parties involved in the HCP negotiations has, in effect, stymied important progress in resolving key relicensing issues for the Rocky Reach Project and has apparently prevented NMFS from completing Section 7 consultations with Chelan PUD and FERC. If biological opinions were issued on the Rocky Reach and Rock Island Projects, the DEIS alternatives would be fundamentally changed.

Given the bad faith of Chelan PUD to "conditionally implement" the HCP through cooperation and consensus of the JFP, NMFS should immediately complete a Section 7 Biological Opinion and declare jeopardy on the operation and structural configuration of the Rocky Reach and Rock Island Projects. Upper Columbia stocks, both listed and unlisted, are in extremely poor status, and cannot withstand protection delays while the HCP process grinds onward at an excruciatingly slow pace.

CRITFC does not support DEIS Alternative 3 for the above reasons. CRITFC recommends that NMFS and the Department of Interior retain their authorities under various statutes and laws to prescribe, in consultation with the tribes, meaningful protection, mitigation and compensation measures for the PUD hydroprojects, as offered in Alternative 2. This is critical to immediately increase anadromous fish survival and productivity to avoid extirpation and to fully recover Upper Columbia populations to a level that provides for tribal and non-tribal harvestable surpluses.

Sincerely,

Don Sampson
Executive Director

RE: **Comments on the Draft Environmental Impact Statement (DEIS) regarding the proposed Anadromous Fish Agreements and Habitat Conservation Plans (HCPs) for the Wells, Rocky Reach and Rock Island Hydroelectric Projects.**

Dear Mr. Dach:

The Confederated Tribes of the Colville Indian Reservation (Colville Tribes) has reviewed the DEIS regarding the *Proposed Anadromous Fish Agreements and Habitat Conservation Plans (HCPs)* for the Wells, Rocky Reach and Rock Island Hydroelectric Projects. We appreciate the opportunity to review the document and provide the following comments. The Colville Tribes has been a participant in the process of this HCP development since it's initiation more than six years ago. We have in good faith attempted to support and move the process forward towards meeting the recovery, protection and conservation of Mid-Columbia anadromous fish resources which are so important to the Colville Tribe's subsistence, religious, ceremonial and cultural way of life. However, since last year it has become evident to the Colville Tribes that several unresolved issues exist with respect to the HCPs which place in question whether they fall short of providing the necessary protection, conservation and recovery for Mid-Columbia River anadromous fish resources. We will discuss these issues and the uncertainties they create for the HCP alternative in our comments below.

General Comments

- The most important element of the HCP alternative from the Colville Tribes perspective is the overall performance standard of 100% which is known as the No Net Impact standard. This standard in our view is the foundation of the HCPs and is intended to achieve no net impact for all plan species at each project. It includes both a project survival requirement of 91%, which includes a 95% juvenile dam passage survival, and a 9% compensation requirement for unavoidable project mortality, which is provided through 7% hatchery and 2% habitat compensation programs. During the late stages of HCP development, the National Marine Fisheries Service (NMFS) determined that they could no longer support the 7% hatchery compensation requirement as had been identified during the prior 4 years of HCP development. They were concerned

CTCR

1

with the potential impacts to ESA recovery from hatchery programs and therefore could not guarantee the 7% compensation level. We question this decision by NMFS, especially since their assessment (QAR) of implementing only the HCP survival and tributary improvements (no hatchery compensation measures), indicate that these HCP actions would not meet interim recovery levels for either spring chinook or steelhead. The reluctance on the part of NMFS to guarantee the 7% hatchery compensation level creates a major concern for the Colville Tribes and as long as the No Net Impact standard remains unresolved, the Colville Tribes will not support the HCP alternative.

- A major objective of the HCP alternative is to protect and conserve both listed and non-listed anadromous fish plan species which include: spring run chinook salmon, summer/fall chinook salmon, sockeye salmon, coho salmon and steelhead inhabiting the Mid-Columbia River basin. The hatchery compensation plan for one of these plan species, Okanogan River sockeye salmon, is inconsistent with this objective. This plan species, and only this species, is subject to a substitution measure, which allows sockeye smolt production to be eliminated and substituted by summer/fall chinook. The Colville Tribes oppose this action and voiced concern on many occasions during the HCP development process that they would not support an action, which substituted one plan species for another. However, one of the HCP proponents, Douglas County PUD continues to pursue this action and just recently reminded the Colville Tribes of their ability to continue this action within the HCP process. Okanogan River sockeye are an important anadromous fish species to the Colville Tribes and we are concerned about the well being of this species in light of the unavoidable losses caused by the Wells Hydroelectric Project. We will not agree to an HCP that contains measures that allow unavoidable mortality of Okanogan River sockeye to be compensated by substituting hatchery production of sockeye for that of another species. 2

- The verification of survival standards also concerns the Colville Tribes. Currently, technology is not available to sufficiently conduct all of the survival evaluations required in the HCPs for all plan species. The HCPs propose to conduct representative survival studies for yearling chinook and steelhead and then develop indirect methods to measure compliance of other plan species during Phase I. Efforts would continue to determine more direct compliance during later phases but no mandatory survival studies to verify survival standards of all plan species is required. This strategy tends to suggest to the Colville Tribes that there is a lack of commitment on the part of the proponents to conduct survival studies on any plan species except the listed species. They want a 50-year agreement that supposedly will conserve, protect and recover all anadromous plan species, both listed and unlisted, but in reality the survival studies only deal with listed species. Why would the Colville Tribes commit to a 50-year agreement that would affect the Tribe's ability to raise other anadromous fish issues that may become important to the 3 4 5

Tribe during the next 50 years, when only listed species will be the focus of this HCP. We can almost certainly obtain those same assurances with the Section 7 Consultation Alternative without having to commit to a 50-year agreement. This issue is discussed in more detail in specific comments, 2, 3, and 4 below.

Specific Comments

* We note that survival estimates and monitoring efforts appear to be heavily reliant upon marking programs (PIT tags, balloon tags, radio tags). We feel that although theoretically this may be sound, in practice, large scale marking programs as needed to assess both juvenile and adult passage rates and survival may not be possible due to the scarcity of test animals. We offer
6 no solution to this situation but question, given the stress and mortality associated with fish handling and marking, the practicality of marking large numbers of Plan or Permit species for either phase I or II evaluation or phase III monitoring efforts.

We also note that survival studies utilizing PIT tags require downstream recovery locations equipped with passive interrogation systems. At present, the primary recovery locations for PIT tagged fish used in survival studies at Wells, Rocky Reach, and Rock Island Dams would be at McNary and John
7 Day Dams. Due to the great distance between the release and the recovery locations and associated in-river mortality, precise survival estimates would require the release of large numbers of PIT tagged fish. For example, approximately 70,000 yearling chinook were required to evaluate survival rates at Rocky Reach and Rock Island Dams in 1998 and even with these large numbers of marked fish the precision of survival estimates were lower than anticipated due to lower than expected recovery rates. Recovery rates for
8 sockeye and zero age chinook would likely be lower than that of yearling chinook, requiring excessive, possibly unrealistic, numbers of PIT tagged fish to conduct the survival studies.

It is our understanding that turbine mortality studies with balloon tags are normally conducted by releasing individual marked fish through turbine intakes. Although we agree that this type of assessment does provide some level of insight into the effects of turbine passage on juvenile salmonids, we do not believe that this assessment technique adequately represents the
9 simultaneous passage of thousands of juveniles through turbine intakes as occurs during peak outmigration periods. We therefore suggest that other evaluation techniques be used in conjunction with balloon tag studies to adequately assess juvenile turbine passage mortality.

* We have noted that the HCPs rely heavily on marking programs to verify compliance with survival standards and have questioned that adequate numbers of test fish will be available to conduct these evaluations. We also note that under "Phase I Measurement and Evaluation, section d" in each HCP it states:

10

"If the differences between the study results and the District's performance standard being measured are not statistically significant, then the District's performance standard has been met."

We object specifically to this clause as non-significant differences, which would be interpreted as meaning that the District's have met their performance standards, can easily result from a combination of inadequate numbers of marked fish or lower than anticipated recovery rates.

* We acknowledge the use of surrogate species (i.e., yearling fall chinook for spring chinook) in marking studies as an alternative to marking endangered species. However, we question that yearling chinook and

11

juvenile steelhead adequately represent the FPE or mortality rates of juvenile sockeye or zero age chinook summer migrants. We note that Fish Guidance Efficiency research at COE projects has consistently shown both sockeye and zero age chinook to have considerably lower Fish Guidance Efficiencies (FGE) compared to those of yearling chinook and steelhead. In addition, descaling and mortality rates for juvenile sockeye are typically higher than those of yearling chinook and steelhead at Columbia River COE projects. We also note that both turbine passage mortality and predator susceptibility for juvenile sockeye and zero age chinook are likely different from those of yearling chinook and juvenile steelhead. We suggest that FPE and survival

12

estimates derived through the use of tagging studies with yearling chinook and steelhead likely will overestimate FPE and survival for the other Plan species (sockeye, zero age chinook, and possibly coho) under Alternative 3. In addition, because adult passage studies have not been completed for each of the three hydroelectric projects and juvenile studies have not been completed for each of the Plan species, the only standard to which project survival can be

13

measured under Alternative 3 are survival studies of juvenile steelhead and yearling chinook. We further note that the yearling chinook used in such studies were yearling fall chinook as a surrogate for yearling spring chinook. We suggest that both juvenile and adult passage and survival evaluations need to be completed for all Plan species and used to evaluate and monitor compliance standards for all three HCPs. However, we also question the practicality of completing such work and repeating such work on a timely basis as necessary for either evaluation or monitoring activities.

14 * Under Alternative 3, the HCPs indicate that the evaluation portion of Phase I will occur over a three year period. We question that all five Plan species could be evaluated during such a short period of time.

15 * We applaud the consideration given to adult fallbacks in both Alternatives 2 and 3. We are aware of 1999 radio tracking work conducted with adult steelhead in the Mid-Columbia which, when the data analysis is complete, will provide some reference on adult steelhead migration behavior including fallback at mainstem projects. We are not aware of work specifically designed to address: 1) kelt passage in terms of guidance efficiency, direct and delayed mortality (note that kelts are downstream migrants and not true fallbacks) or 2) fallback guidance efficiency, direct and delayed mortality. We believe this to be an outstanding unresolved issue, which has not been adequately addressed in either the action areas of the Wells, Rocky Reach, or Rock Island Projects or elsewhere in the Columbia Basin.

16 * We agree that Pacific lamprey, although currently not listed as a Plan species, may benefit from tributary improvements as part of Alternative 3. Pacific lamprey currently are the focus of dam passage research elsewhere in the Columbia Basin due to declining populations. Currently, little is known of juvenile lamprey FPE or turbine passage mortality and we therefore consider this to be an outstanding unresolved issue. We further request that due to the cultural importance of lamprey to the Colville Tribes, that Pacific Lamprey be included as a Plan species under Alternative 3.

17 We also note that restoration of lamprey populations is consistent with the objectives for basin level biological performance as indicated under the "Anadromous Fish Losses" section of the Northwest Power Planning Council's 2000 Columbia River Basin Fish and Wildlife Program.

"*Halt declining trends in salmon and steelhead populations above Bonneville Dam by 2005. Obtain the information necessary to begin restoring the characteristics of healthy lamprey populations.* " (Page 18)

18 * Similar to Pacific lamprey, white sturgeon are another anadromous species, which have been affected by the development of the hydrosystem but are not listed as a Plan species. The DEIS mentions little about white sturgeon other than that little is known about their population status. Sturgeon are an important species to the Colville Tribes and we believe the most likely impacts to sturgeon populations have been loss of spawning habitat due to inundation and blocked migration due to dam construction. We consider the effect of hydroelectric development on white sturgeon populations in the Mid-

Columbia to be an outstanding unresolved issue, and request that white sturgeon be included as a Plan species under Alternative 3.

19

* We note that natural river drawdown and dam removal, although not considered to be viable alternatives in and of themselves, would appear to remain as possible actions available to be evaluated through the FERC relicensing process under Alternative 2 but, except as where specifically noted, not under Alternative 3.

Alternative 2

"Although natural river drawdown is not an option under the existing FERC licenses, it could be evaluated during relicensing procedures. The current FERC licenses expire in 2006, 2012, and 2028 for Rocky Reach, Wells, and Rock Island dams, respectively." (Page S-11)

"In addition to the required research and monitoring efforts, the following measures, or combination of measures, could potentially be required as a result of the Section 7 consultations:...

... Other non-power actions (i.e., drawdown) if the combination of project and habitat related measures have not adequately addressed the decline of listed species." (pages 1-14 through 1-15

Dam removal is extremely controversial, and can only be legally mandated at project relicensing." (page 2-45)

Alternative 3

Under Alternative 3, it would appear that drawdown or dam removal are actions that could be ordered by FERC as part of the relicensing process,

"HCP's also have termination provisions if the performance standards are not achieved. An HCP could be less than 50 years under the following circumstances:...

...FERC orders removal or drawdown of the project." (page *2-33)*

But, given ...

"*It is the intention of the PUDs that mitigation measures agreed upon as part of the HCP be consistent with, and where possible form the basis of subsequent FERC license articles developed to address impacts on Anadromous salmonids."* (page 2-33)

it would appear that such an order from FERC would be unlikely.

A special provision has been made to allow for drawdown or dam removal without termination of the HCP but requires mutual agreement between the services and the PUDs.

"Any party to the HCP (except the PUDs) may elect to withdraw from the agreement, based on the non-compliance provisions of the HCP agreements. However, NMFS and USFWS will not exercise their right to withdraw from the HCP if the PUDs have complied with all aspects of the agreement but have not met the survival standards. If mutual agreement is reached between PUDs and the two Federal agencies, the services (NMFS and USFWS) can seek natural river drawdown, dam removal, and/or non-power operations without withdrawing from the agreement or suspending or revoking the Incidental Take Permit. " (page 2-33)

We further understand that, based upon the conditions as stated in the "Assurances" sections of the HCPs, signatories to the HCP cannot advocate drawdown or dam removal accept as noted above. However, we assume that non-signatory parties could request an evaluation of drawdown or dam removal as part of the FERC relicensing process for each project.

We request verification that our understanding is correct.

20

* We note that significant differences related to hatchery production exist between Alternatives 2 and 3. Changes in hatchery production are not specifically identified under Alternative 2 although hatchery production may be refined (increased or decreased) based upon effects on listed species.

Under Alternative 3, the HCPs provide 7% hatchery compensation for unavoidable project mortality. We understand from the statement below that the 7% hatchery compensation for unavoidable project mortality is above and beyond that provided for original project inundation (i.e., baseline conditions).

"HCP Baseline Conditions. The HCP's do not address impacts resulting from original project construction or mitigation from past damages. Mitigation measures for these impacts have already been implemented as part of the existing licenses. Prior activities are not considered an action subject to additional mitigation beyond license requirements unless they are considered to cause a continuing "take" of listed species as defined under the Endangered Species Act."

Existing hatchery production levels are initially assumed to provide adequate compensation for original inundation by the projects. Therefore, the baseline is considered to be the existing conditions." (page S-16)

We interpret these statements as meaning that hatchery production would be increased under Alternative 3 to provide an additional 7 percent compensation above baseline conditions (conditions present as of January 1997) unless NMFS determines that such production results in jeopardy to listed species.

However, current PUD funded hatchery production includes compensation for both inundation losses (baseline) and for some level of unavoidable project mortality. For example, Rock Island and Wells Settlement Agreements also provide for passage loss through Eastbank and Methow Hatchery Programs. So at least some of the 7% is already being provided under the existing settlement agreements and the PUD's may be providing additional compensation above what is currently required. Because of this, it is difficult to discern from the DEIS how hatchery production levels for each of the Plan species will change under each HCP. Will the Douglas PUD funding for 14% hatchery compensation be reduced with the adoption of the Wells HCP?

21

In addition, the DEIS states,

"During the development of the HCPs, NMFS determined that the 7 percent hatchery compensation levels might adversely affect wild salmon populations under certain conditions. For example, it may be necessary to use adult salmon and steelhead that are not adapted to the local habitat conditions in order to produce enough juvenile fish to meet the 7 percent compensation level. In order to ensure that these compensation levels do not effect the long -term health of the wild populations, all fish produced under this program must be from local stocks. Therefore, until the specific details of the compensation programs are developed, including identification of appropriate broodstock, maximum percentages of the wild population that can be trapped for broodstock, and the total number of fish that can be produced through artificial means, NMFS can not guarantee that the 7 percent compensation level will satisfy Endangered Species Act requirements and no net impact would not be achieved." (page S-26)

22

It would appear that under Alternative 3, current hatchery production levels could be reduced if they:

- currently exceed the 7% unavoidable project mortality compensation level, or
- are determined to jeopardize the recovery of ESA listed stocks, or
- must rely on insufficient numbers of local broodstock.

We request clarification as to specifically how hatchery production for each Plan species will change from current production levels under each of the HCPs.

23 We note that under "Initial Production Capacities" in the HCPs for the Wells, Rocky Reach, and Rock Island Projects, production of coho is not mentioned. As a Plan species, coho need to be included in the 7% hatchery compensation. As native coho salmon are considered to be extirpated from the Mid-Columbia River region, how will hatchery production levels be established for this species under the HCPs?

24 * We understand that under Alternative 2 a biological opinion will be created and will be a "living document" that will be updated at any time that new information becomes available.

"Specific measures required in the initial biological opinion may be modified or new measures may be required as a result of this process. In addition, if other species were listed under the Endangered Species Act, additional consultation practices would occur." (page 2-27)

We note that under Alternative 3,

"The requirements of Section 10 of the Endangered Species Act provide the guidelines for HCP preparation. The information within each of the HCP's includes the following:.. Proposed mitigation and enhancement measures to address unresolved and unknown future issues (note: an adaptive management plan to address changing circumstances and unknown future events addresses this issue in the proposed HCPs)." (page 2-32)

However, under Alternative 2,

"National Marine Fisheries Service has the legal authority to determine the actions necessary to ensure the survival and recovery of listed species. This includes determining the most appropriate measures to be taken at each project, the necessary level of survival at each project, determining the most appropriate data to be considered when evaluating survival; and modifying the measures as needed if species continue to decline.... Under Section 7, NMFS has a legal responsibility to provide the benefit of the doubt to listed species with respect to gaps in the information base.

If FERC or the PUDs disagree with the NMFS's decisions under this process, lengthy legal proceedings may ensue." (page 2-53)

Under Alternative 3,

"According to provisions in the HCP's, the authority to determine the appropriate protection measures for all of the Plan species, including Endangered Species Act species, fundamentally shifts away from NMFS under Alternative 3 (HCPs) once the incidental take permit has been issued. During Phase I of the HCPs, the PUDs

would have the ultimate authority to determine the measures necessary to achieve the survival standards. During Phase II, a Coordinating Committee (comprised of the PUD responsible for the HCP, NMFS, and each of the signatories to the agreement), jointly decides on the appropriate measures. If the Coordinating Committee cannot reach consensus, the PUDs may continue to determine the appropriate measures unless the matter is addressed through the dispute resolution process."

"The party bringing an issue to dispute resolution must prove its case by a preponderance of the evidence. There is no requirement to provide the benefit of the doubt to the species of concern with respect to gaps in the information base and NMFS has no authority to determine what constitutes the best available information to be utilized in support of any decisions. The dispute resolution process is limited to under 5 months, ensuring that lengthy legal disputes would not occur, and decisions reached through the dispute resolution process are binding." (page 2-53)

We note that both alternatives provide for some level of adaptive management and that adaptive management under Alternative 2 would only apply to listed species whereas under Alternative 3 adaptive management would apply to all Plan species.

We further note that although Alternative 3 appears to provide an expedited mechanism for settling disagreements, the emphasis shifts away from providing the benefit of the doubt to the species of concern. We recognize that the species of concern would include all Plan species under Alternative 3 as opposed to just ESA listed species under Alternative 2. However, given that substantial data gaps pertaining to fish passage and survival do exist and are likely to continue to exist in the future, we doubt that a "*preponderance of evidence*" can be readily assembled to support a resolution in favor of the species of concern. We consider this potentially to be a fatal flaw in Alternative 3, as non-compliance to HCP standards must be proven under the dispute resolution process, presumably through some mark recapture study about which we have already expressed concerns (see Comments 2-4). If such proof is not available, then actions detrimental to the species of concern will be allowed to continue.

25 We believe that lack of direct evidence should not constitute assumed compliance with survival standards.

26 * It would appear that tributary habitat enhancement is possible under both Alternatives 2 and 3. Under Alternative 2, such actions are not expected but could be required if other on-site actions do not lead to the recovery of the two listed species.

"In addition to the required research and monitoring efforts, the following measures, or combination of measures, could potentially be required as a result of the Section 7 consultations:...

7. Improvements in tributary habitat if the project specific measures have not adequately addressed the effects of project operations." (pages 1-14 through 1-15)

Under Alternative 3, a Tributary Conservation Plan and Plan Species Account would be created to compensate for 2 percent of the unavoidable project mortality. Contributions to this account would be made by the PUDs on behalf of each project. We note that for the Wells Project:

"For the Wells Project, the Douglas County PUD would make an initial contribution to the account of $991,000 (1998 dollars adjusted for inflation). If juvenile dam passage survival after three years of evaluations remains greater than or equal to 95 percent, the district would make annual payments of $88,089 (1998 dollars) throughout the HCP term or would pay$1,321,333 (equivalent to 15 years of annual payments), deducting the actual costs of bond issuance and interest. If juvenile dam passage survival is less than 95 percent, the Douglas County PUD shall contribute an additional $991,000 and increase the annual funding to $176,178, or make an up front contribution of $2,642,667 (equivalent to 15 years of annual payments in 1998 dollars), deducting the actual costs of bond issuance and interest." (pages 2-38 through 2-39)

We have several concerns related to this clause.

27 Per our previous comments related to the heavy reliance of the HCPs on the results of marking programs, to ensure that the 95% juvenile passage survival standard is accurately measured, evaluations must be conducted using each of the Plan species and not through the use of surrogates (Comment 3). As

28 indicated in Comment 4, we once again question that survival studies for each of the five plan species can be completed in a three-year period. As indicated in Comment 2 we object to the clause "*If the differences between the study results and the District's performance standard being measured are not statistically significant, then the District's performance standard has been met.*" In this case non-significant differences would result in a reduction in

29 Douglas PUD contributions to the Plan Species Account.

In addition, during Phase III of the HCP, juvenile survival is to be periodically re-assessed. If the 95% survival standard were to be met under Phase I, no provision appears to exist to allow additional monetary compensation if

30 juvenile survival is determined to drop below the 95% standard as measured during Phase III monitoring efforts.

We suggest that a statement such as the following should be added:

"In the event that the 95% survival standard is met for each of the Plan species during the phase I three year evaluation period, but subsequently determined to decline to a survival level less than 95% for any of the Plan species during Phase III monitoring activities, Douglas County PUD will

provide an additional $991,000 and will increase annual contributions from $88,089 to $176,178. The $991,000 (1998 dollars) will be a one time additional payment required for non-compliance with the 95% juvenile survival standard. The increase in annual contributions from $88,089 to $176,178 will continue until further monitoring assessments determine that the 95% juvenile survival standard is met for each of the Plan species. Douglas County PUD may provide an additional $1,321,333 one-time payment in lieu of the additional annual $88,089. "

We further note that the annual payments would begin "*...after three years of evaluations...* " In addition *"The HCPs set an initial 5-year period for the PUDs to meet the 95 percent juvenile dam passage survival standard, followed by up to three years of evolutions.*" From this, we conclude that the annual payments to the Plan Species Account may not begin until eight years after the start of Phase I. We suggest that the initial payment of $991,000 be increased to $1,695,712 (1998 dollars) to account for the eight years of annual payments of $88,089 that will be missed during Phase I.

31

* We question and seek clarification as to what happens if an affected party does not sign the HCPs under Alternative 3. Our understanding is that because the HCPs are voluntary ESA compliance efforts on the part of the PUDs, that technically they need only include the services (NMFS, USFWS), FERC and the PUDs themselves. It would appear that non-signatories couldn't participate as members (either voting or non-voting) on either of the Coordinating Committees or the Hatchery Committee. The same is generally true for the Tributary Committee, however, a non-signatory party could potentially be selected to serve as an expert non-voting member by the Tributary Committee.

32

* Within the mid-Columbia River, total dissolved gas (TDG) supersaturation is the foremost water quality concern. It causes migration delays and mortality from "gas bubble disease". Most of the TDG is a result of spilling done to aid downstream fish passage or to manage excessive flows. The high TDG levels persist well downstream of the project area where they originate. Currently, spill deflectors are a voluntary mitigation measure, and WDOE grants waivers to the dams for exceeding TDG levels.

33

We note that spill remains the primary juvenile passage strategy at Rock Island Dam under Alternatives 2 and 3. Spill is also the primary juvenile passage strategy at Wanapum and Priest Rapids dams. We are concerned that increased volumes of spill at Rock Island Dam, as potentially advocated under both Alternatives 2 and 3, may result in increased Total Dissolved Gas levels, which may cripple or preclude spill operations for juvenile passage at the Wanapum and/or Priest Rapids projects.

Given the larger water volumes stored and/or spilled at Chief Joseph and Grand Coulee dams, TDG and other water quality problems originate
34 upstream of the area the DEIS considers. Just as tributaries to the Mid-Columbia are included in habitat and water quality considerations, the effects of the upstream dams should be part of any HCP.

More specifically, the DEIS does not mention any specifics with respect to gas abatement structures at Chief Joseph or Grand Coulee dams. In addition, the large storage behind Grand Coulee Dam (in terms of both areal extent and temporal duration) allows a thermocline to develop during warmer months. The increased temperatures exacerbate the effects of total dissolved gas supersaturation. High water temperatures have other adverse effects on salmonids; these are discussed in a separate section.

Wells: A controlled spill with modified spill bays is currently used for
35 juvenile fish passage, and is relatively successful, having an overall survival rate of 98 percent. The spill form is not clear in the DEIS -- is it a step-pool cascade structure? If so, it might result in relatively lower TDG levels resulting from spills (because of decreased vertical drop). The DEIS states that TDG levels "sometimes" exceed state standards; in fact, the Mid-Columbia is 303(d) listed for this parameter because of high TDG levels below Wells Dam. Could the goal of improved fish passage and WDOE's
36 water quality responsibility to reduce TDG justify a more elaborate structure to accommodate spills (and fish passage)? There is no mention in the DEIS of spill deflectors at Wells Dam, and there have been no new structural modifications there since 1990.

Rocky Reach and Rock Island are part of the same reach for WDOE water quality designations, and are currently listed for TDG, as well as temperature and bioassay levels. Rocky Reach has a spill program to aid juvenile fish passage (and perhaps adult fall-backs and kelts); the program provides for spill levels equal to 15% of daily flows during spring and 10% during summer. In addition, a turbine bypass system (for fish passage) was installed
37 in 1994 and is still being modified. There is no mention in the DEIS of spill deflectors at Rocky Reach Dam.

Rock Island: As mentioned above, TDG, temperature, and bioassay levels are 303(d) listed in the reach that includes Rock Island. Currently, there is a primitive orifice bypass used for spill purposes, and spill is purchased with a
38 conservation account. Thus, timing and magnitude of spill may be dependent on available funds. Given the effect of spill on TDG, this might also restrict options for resolving water quality problems.

A bypass system has never been adequately developed at Rock Island. The DEIS states that several modifications for fish passage are being considered: a forebay guidance curtain, testing spill configurations, turbine bypass systems,
39 and other options for juvenile bypass. Consideration of water quality effects

(especially TDG), including opportunities for improvement, should be part of all bypass development plans.

40 There is no mention in the DEIS of spill deflectors at Rock Island Dam. Both Rock Island and Rocky Reach dams have TDG and gas bubble disease monitoring mentioned as part of Alternative 2, yet there is no planned response to those problems.

41 * The Washington Department of Ecology is in the process of revising the Water Quality Standards for Surface Waters of the State of Washington (Chapter 173-201A WAC). The revised standards, if adopted, will be more stringent with regards to water temperature and dissolved oxygen concentrations. Water body classifications will be "use-based" with specific attention paid to use by salmonids. There do not seem to be provisions within the DEIS or the HCPs to account for or integrate these more stringent water quality standards.

42 For example, the DEIS acknowledges violations of current state temperature standards with maximums as high as 23.8°C and three-month averages ranging from 10.0 to 18.8°C. Temperatures in Tables 3-5 and 3-6 are often in excess of the proposed revised WDOE standards for seasonal daily maximums and moving 7-day averages for daily maximums. For salmonid rearing and migration waters, the proposed water temperature standard is 15°C (moving 7-day average of daily maximums) with no single daily maximum to exceed 17.5°C from June 1 through September 14.

DO levels are linked to temperature; the DEIS consistently states for all three dams that "DO levels do not *typically* drop below 8.0 mg/L" but under the proposed revised standards, this only applies from June 1 through September 14, and only for rearing and migration waters. For salmonid spawning waters, average daily DO levels cannot fall below 10.5 mg/L from September 15 through May 31, with no single daily minimum falling below 9 mg/L.

We also note that the Wells project has inundated the lower 17 miles of the Okanogan River resulting in elevated water temperatures for this reach. Elevations in water temperature have delayed adult sockeye migration into the Okanogan River and possibly resulted in an elevation in pre-spawn mortality rates. This needs to be addressed in the HCP for the Wells Project.

43 * Fall and summer chinook in the Mid-Columbia River are generally considered to outmigrate during the first year of life as zero age summer migrants. However, it is our understanding that a high percentage (46%-78%, John Sneva, WDFW, personal communication 3/21/01) of the Wenatchee River adult summer chinook show scale growth patterns indicative of an additional year in fresh water. These fish may be relatively small in number but an important component of adult returns. In addition, these fish may over-

winter in hydroelectric reservoirs and therefore may arrive at hydroelectric projects at any time during the year such as late summer or early spring.

Summer chinook are not an ESA listed species and therefore not addressed in Alternative 2. They are plan species under Alternative 3, but the holdover component of the juvenile population does not appear to be considered, most likely because this characteristic has not been adequately assessed. We further note that the 95% dam passage survival standard for juveniles under Alternative 3 applies to 95% of the run period for each Plan species, which may not provide adequate protection for holdover summer chinook. We consider this to be an outstanding unresolved issue.

Thank you for the opportunity to comment on the HCP DEIS. If you have questions about our comments or need further clarification, please contact Joe Peone, Director of the Colville Tribal Fish and Wildlife Department at 509 634-2113.

Sincerely,

for Dale Louie

Re: Draft Environmental Impact Statement for the Mid-Columbia Anadromous Fish Agreements and Habitat Conservation Plans

The Confederated Tribes of the Umatilla Indian Reservation (CTUIR), Department of Natural Resources, offers the following comments on the Draft Environmental Impact Statement (DEIS) for the Anadromous Fish Agreements and Habitat Conservation Plans (AFAs/HCPs) for the Wells, Rocky Reach and Rock Island Hydroelectric Projects prepared by the National Marine Fisheries Service (NMFS). Our comments incorporate by reference the comments of the Columbia River Inter-Tribal Fish Commission (CRITFC), submitted on behalf of the Columbia River Treaty Tribes.[1] We also incorporate by reference all prior correspondence and comments submitted by the CTUIR and CRITFC on our behalf, such as Scoping Comments dated February 5, 1999.

[1] The Columbia River Treaty Tribes include the Confederated Tribes of the Umatilla Indian Reservation, the Nez Perce Tribe, the Confederated Tribes of the Warm Springs Reservation of Oregon, and the Confederated Tribes of the Yakama Nation. The four tribes possess rights reserved by treaties with the federal government to take a fair share of the fish destined to pass our usual and accustomed fishing places. Among these fish are the anadromous species that originate in the Columbia River and its tributaries, including the Mid- and Upper Columbia.

CTUIR

Introduction

The construction and continued operation of the Wells, Rocky Reach and Rock Island dams have greatly impacted the rights and resources of the CTUIR and its members. They have harmed anadromous fish populations and significantly altered their habitat. These fish and their habitat have been a critical part of tribal existence for thousands of years. Even when faced with the overwhelming power and unfair bargaining position of the United States during negotiations over the Treaty of 1855, the Cayuse, Umatilla and Walla Walla tribes were adamant in specifically securing the pre-existing right to fish at all usual and accustomed places. Retaining the right to continue their traditional fishing practices was a primary objective of our ancestors when they signed the Treaty.[2]

1 While the Draft AFAs/HCPs may have been developed pursuant to provisions of the Endangered Species Act (ESA), NMFS (and other federal agencies) should not lose sight of the fact that they are subject to additional, higher duties and obligations such as those imposed by the Treaty of 1855. In this process and all others involving salmon and steelhead in the Columbia River Basin, the federal government must adhere to the paramount goal of protecting, enhancing and restoring anadromous fish and their habitat so as to lead to sustainable, harvestable fish populations consistent with tribal Treaty Rights. The United States must honor those Rights, ensure the free exercise of those Rights by tribal members, and fulfill its Trust Responsibility toward tribal trust resources.

The DEIS And Underlying AFAs/HCPs Do Not Adequately Honor Treaty Rights Nor Fulfill Federal Trust Responsibility

2 Unfortunately, the Draft AFAs/HCPs and the DEIS examining them indicate that the federal government has fallen far short of above goal thus far. Merely striving to "de-list" species currently listed under the ESA is insufficient. It may serve as an initial step in the right direction, but our Treaty demands more. Other laws have separate mandates, and also require more rigorous results, such as the Federal Power Act, the Northwest Power Act and the Clean Water Act, for example.

3 The Proposed Action (Alternative 3) does not fulfill the federal Trust Responsibility to the CTUIR or other tribes. The Draft AFAs/HCPs lack assurances that 7% hatchery compensation will be achieved, which we believe is essential in order to eventually enjoy healthy, harvestable fish populations. The federal government seems willing to offer "No Surprises" assurances to

4 other parties, but is unwilling to extend equivalent ones to the tribes. The United States is also reluctant to include provisions assuring the tribes that nothing within the AFAs/HCPs will be

5 used against us in possible future litigation, should any arise. Finally, the federal agencies also may be prevented from taking additional necessary recovery and rebuilding measures in the event fish resources continue to deteriorate despite implementation of the AFAs/HCPs.

---

[2] *See Tulee v. Washington*, 315 U.S. 681, 684-85 (1942); *United States v. Washington*, 443 U.S. 658, 664-69 (1973).

The Agreements Are Not Ripe For Review

6 Before proceeding further, we should note that we seriously question whether it is appropriate for the AFAs/HCPs to be subject to environmental review at this time. The parties to the negotiations agreed that the documents were not to move forward in the absence of a "final package" acceptable to all the parties. At present, this is not the case—not everyone is "on board" with the draft documents, in particular the tribes. Unfortunately, the DEIS apparently presumes that the AFAs/HCPs are final, official, and suitable for implementation, when in fact
7 there are as of yet no signed HCPs and no ESA Section 10 permits.[3] Thus, the region should be proceeding under regular relicensing, for dams such as Rocky Reach, until the HCP process has reached a satisfactory conclusion.

The DEIS Contains Inaccuracies And Promotes Misperceptions About Tribal Positions and Involvement

8 The DEIS inaccurately portrays the CTUIR's position on a number of issues. While the CTUIR and others offered substantial concessions during negotiations in exchange for the incorporation of certain measures in the AFAs/HCPs, those measures were not included in the Draft AFAs/HCPs submitted to NMFS. Thus, no valid, binding agreements have been reached between the parties as of this date. Consequently, the DEIS cannot and should not imply or suggest that the CTUIR has agreed to the sum of contents of the AFAs/HCPs.

9 In the past, the CTUIR informed NMFS that it should not create the appearance that the CTUIR fully supported the AFAs/HCPs or any portion of them, specifically asking that our name be removed from certain documents.[4] This was not done, and explanations in the DEIS relative to the CTUIR's positions do not adequately convey the fact that we have not agreed to the AFAs/HCPs in their present form.

10 The CTUIR also seeks additional assurances in the AFAs/HCPs addressing not just hatchery and production, as the DEIS mentions. There are other guarantees that are as important to us as those sought by the Public Utility Districts (PUDs), and are required before we can agree to the
11 AFAs/HCPs. Finally, there are assertions that the "No Net Impact" (NNI) concept was developed with tribal biologists, implying wholesale tribal acceptance when that was not the case.[5]

Halfmoon, Vice Chairman, Board of Trustees, to Mr. William J. Stelle, Jr., Regional Director, Northwest Region, National Marine Fisheries Service, Dec. 9, 1998.

[5] *See* DEIS, p. 2-35.

NMFS Has Not Complied With The Secretarial Order In Developing The AFAs/HCPs Or The DEIS

12 In participating in the development of the AFAs/HCPs and producing the DEIS evaluating them, NMFS has failed to comply with the 1997 Secretarial Order of the Secretaries of Commerce and Interior entitled "American Indian Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act." The Secretarial Order requires the agencies to interpret and implement the ESA in a manner that harmonizes the tribal rights and our sovereignty with the Secretaries' duties under the ESA. It also requires that the agencies ensure that tribes not bear a disproportionate share of the conservation burden for listed species. The DEIS must account for the Secretarial Order's requirements, but does not.

The DEIS And Underlying AFAs/HCPs Have Additional, Substantial Deficiencies

The DEIS and the AFAs/HCPs also suffer from numerous other serious flaws that render them inadequate and unsupportable. Some of these are summarized below:

13 The DEIS neglects to address several important legal issues, such as compliance with Clean Water Act requirements for water quality and quantity. The document acknowledges that the projects exceed water quality standards for temperature, yet it contains no information about how this problem could be addressed under the alternatives.[6]

14 The DEIS lacks meaningful analysis of survival, recovery and rebuilding. Quantitative detail is absent in both the AFAs/HCPs and the DEIS on how listed species would be impacted by implementation of the AFAs/HCPs. While the DEIS mentions the Quantitative Analytical Report (QAR) produced by NMFS, it does not incorporate its results into the alternatives analysis. This is a significant oversight in that, according to NMFS's own data in the QAR, measures in addition to those set forth in the AFAs/HCPs will be necessary for recovery:

> "Even under the most optimistic scenarios . . . regarding future survival rates and the effectiveness of supplementation, additional survival improvements beyond those projected for the draft HCP actions would be necessary to achieve extinction risk/recovery criteria."[7]

The DEIS essentially ignores the QAR's finding that meeting the HCP standards and achieving off-site mitigation "would fall short of meeting survival and recovery criteria under the assumptions that 1980-present conditions will continue."[8] Therefore, according to the QAR, additional measures are going to be required for recovery, but such measures are not required nor allowed by the AFAs/HCPs. The DEIS must more fully and completely address these issues relative to all the alternatives.

---

[6] *See* DEIS, pp. 3-96 to 3-100.

[7] QAR, p. ii.

[8] QAR, p. iii.

15 | Furthermore, the geographic scope of the DEIS is inadequate. It fails to address or analyze
16 17 | cumulative and synergistic effects. It lacks a reasonable range of alternatives. Its "No Action"
18 | Alternative is inadequately described and evaluated. The DEIS's comparison and contrast of Alternatives 2 and 3 is biased and inadequate. The DEIS fails to fully consider and address
19 | potential constraints on federal authorities under various statutes, and difficulties in fulfilling federal Trust Responsibility, associated with adoption of Alternative 3. The assurance of "No Surprises" for the PUDs is inappropriate for HCPs of this type, covering facilities that are
20 | inextricably interconnected with other facilities and activities *not* covered by the HCPs, *all* of which affect the anadromous fish populations at issue.

21 | "No Net Impact" under Alternative 3 is misrepresented in the DEIS, which fails to take into account recent scientific information or uncertainties about funding. Additional NNI issues should be explored as follows:

22 | • Assess potential impacts on species within the first five years of the HCPs, during the time in which NMFS and the U.S. Fish and Wildlife Service are limited in prescribing or preempting the plans of the PUDs;

23 | • Analyze and explain the biological basis for the draft AFAs/HCPs' assumption that 91% survival + 7% hatchery mitigation + 2% tributary mitigation are additive so as to guarantee zero impact on the species;

24 | • Examine the relationship between the NNI standard and long-term stock viability;

25 | • Analyze whether or not the proposed measurement of the performance standard for 95% Juvenile Dam Passage Survival, by measuring juvenile survival over only 95% of the run, ensures a juvenile passage mortality of only 5% such that the draft AFAs/HCPs address full mitigation for take;

26 | • Examine passage impacts to anadromous fish and lamprey and descaling injuries (particularly on sockeye) if screens are installed, and assess whether such impacts are accounted for within the NNI standard;

27 | • Determine what impacts may occur during the time period that elapses before the PUDs actually meet the proposed survival requirements and analyze whether those impacts can or will be appropriately mitigated;

| • Determine impacts on the species should the survival goals never be reached during the term of the AFAs/HCPs;

28 | • Assess impacts on spring migrating Chinook salmon if they are exempted from the 95% Juvenile Dam Passage Survival standard as planned; and

29 | • Provide an accurate evaluation of losses and determine whether the mitigation proposal is supported by adequate data to ensure no unmitigated take.

30 The DEIS also misrepresents the issue of drawdown in its comparison of the alternatives, making it appear to be a much more accessible and available option under Alternative 3 than it actually would be in reality. In truth, it would be virtually "off the table," notwithstanding the status of the fish, whether their numbers continued to decline, or whether the dams were responsible. Drawdown must therefore be given serious consideration under Alternative 2 and should also be analyzed as its own alternative.

31 The AFAs/HCPs lack satisfactory provisions for measuring and evaluating the results if the plans are implemented. The DEIS states, "There is currently no methodology that all parties support for determining the survival of adult fish through the projects."[9] The DEIS improperly refers to
32 existing conditions as the baseline in its assessment of the alternatives, precluding the meaningful examination of the ongoing, lingering effects of prior degradation. A "natural river" baseline is more suitable and appropriate.

33 The DEIS does not give adequate consideration to lamprey and sturgeon. It does not give
34 adequate consideration to the issue of long-term risks associated with Alternative 3.[10] It does not evaluate the alternatives in terms of the widely accepted scientific determination that re-
35 establishment of more "normative" river conditions is essential to long-term salmonid survival. It does not adequately portray tribal economic issues and impacts. It does not adequately inform
36 the public and decision-makers about the requirements and responsibilities of all applicable
37 federal statutes and treaties. It lacks adequate analysis of the off-site mitigation proposals.

Conclusion

38 The DEIS fails to establish that the proposed AFAs/HCPs are sufficient to protect anadromous fish in the Mid-Columbia region. Standards and benchmarks are difficult to assess. Risks and
39 uncertainties remain disproportionately balanced on the backs of the salmon and the steelhead on which we depend for the exercise and fulfillment of our rights, religion, economy, culture and spirit. This seems particularly inappropriate at the moment, given the unwillingness of the federal agencies to carry out many of the very measures that they prescribed for themselves in operating the federal hydrosystem.

40 Plans for configuring and operating the Rocky Reach, Rock Island, and Wells dams should have more certainty as to whether or not standards will be achieved, and whether or not those standards are in fact enough. Significant doubts as to the ability to comply with even minimal ESA requirements are raised; thus, far greater doubts as to satisfying tribal Treaty Rights and fulfilling the federal Trust Responsibility are inescapable.

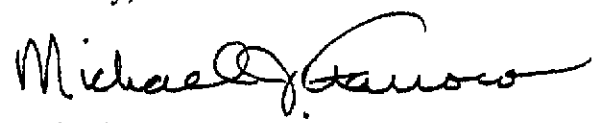
---

[9] DEIS, p 2-41.

[10] See DEIS, p. 4-77.

The CTUIR remains hopeful that the outstanding issues in the AFAs/HCPs can one day be ultimately resolved in a manner that mutually benefits all the parties. Thank you for your consideration of our comments on the Draft Environmental Impact Statement for the Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach and Rock Island Hydroelectric Projects. If you have any questions or wish to discuss any of these matters further, please contact Carl Merkle with our staff at (541) 276-3449.

Sincerely,



Michael J. Farrow

National Marine Fisheries Service
Northwest Region – Hydro Program
525 N.E. Oregon Street, Suite 420
Portland, OR 97232-2737

Greetings:

For the past several years, I have been working with business, government and industry leaders to enhance economic development in North Central Washington. While we have had some successes, there are also many challenges for our region to overcome.

Our region's agricultural industry is suffering, due largely to increasing government and environmental regulations. Our low per-capita income reflects a lack of family-wage jobs. Alcoa, one of this area's two largest industrial employers, is cutting production significantly.

One of our main selling points in keeping existing businesses and attracting new ones is a reliable supply of reasonably-priced electricity from the hydroelectric projects owned and operated by Chelan County PUD.

For the past few years, I have been following the development of the mid-Columbia HCP. It has been my hope that somehow all of the diverse parties involved in this process could come up with a plan to not only protect our fishery resources, but to protect affordable, reliable electricity for residents and businesses in this area. It appears as though the plan that is outlined in the recently released Draft Environmental Impact Statement has a high potential of meeting that goal.

The outcome-based survival standards in the HCP address both performance and compliance in protecting fish. Working with agencies, Indian tribes and other interested parties, the PUD can develop the protection and enhancement measure necessary to achieve the survival goals. Unavoidable losses are compensated through supplementation hatchery production and a significant habitat enhancement fund. Although the fish protection measures will be expensive, it appears that waste will be minimized and our dollars will be channeled into programs that will achieve agreed-upon goals. This is a far better approach than a series of broad-based agency mandates focused on a moving target. Lawyers are the only winners under that scenario.

The HCP provides a measure of certainty for local citizens and businesses and for the other utilities whose customers rely upon Chelan PUD's hydroelectric energy. Meeting the survival standards provides long-term business assurances that fish mitigation requirements won't dramatically escalate in the future. Our PUD should be able to continue to provide the reliable, affordable electricity that we desperately need to sustain, grow and prosper in this region. And, with the ongoing energy crisis in the Northwest, we can ill afford to lose any further generating capacity.

Finally, there is a cooperative plan that makes sense in addressing the requirements of the Endangered Species Act. I support the mid-Columbia HCP and I urge all parties involved to waste no time in implementing this valuable program. Let's keep it moving!

Sincerely,

Jon Eberle
President

CC: Gary Montague, PUD Commissioner

RE. Anadromous Fish Agreements and Habitat Conservation Plans for Wells, Rocky Reach, and Rock Island Hydroelectric Projects

Dear Mr. Dach:

As superintendent of the Entiat School District, I wish to express my concern that Page 2-40 Project Cumulative Effects of the above-referenced plan is inadequate.

It is our position that any further erosion of our tax base would cause irreparable harm to the children and parents of this school district. In our current situation, funds designed to mitigate the loss of fish habitat have seriously impacted the fiscal condition of this school district. The proposal of an additional $45 million for possible land acquisition is obviously a frightening proposition to the officials of this district.

Thank you for providing us an opportunity to express our concern.

Sincerely,

Jeff Davis
Superintendent

Re: Comments on Habitat Conservation Plan

To Whom it May Concern:

Having served in the State Legislature to represent the people of North Central Washington (and to protect the interests of all the citizens of the entire State of Washington), it is with a sense of urgency that I write to endorse the concept of Habitat Conservation Plan (HCP) now being reviewed as a way to deal with the important fishery resources of the mid-Columbia.

This region is faced with extremely serious economic problems. The HCP speaks to economic concerns by offering long-term business certainty on fish spending costs and power rates. It speaks to environmental concerns by providing a balanced approach to compensate for unavoidable losses at dams on the river. It affords quick resolution of disputes rather than plunging issues into the limbo of long, drawn out court battles. It promotes cooperation by establishing review panels involving regulatory agencies and PUD staff. And it sets an example for the rest of the country that illustrates how complicated issues can be resolved through hard work and a collaborative spirit.

With pressures mounting on successful hydropower generators as a result of energy shortages in California and elsewhere, it is increasingly important to protect operators, such as Chelan PUD, who have demonstrated their farsightedness and their competency in managing both the environmental and the generation aspects of their industry. This HCP affords outside regulators a way to do their duty to protect fishery resources while allowing Chelan PUD the

flexibility to find creative and workable solutions that produce results. Such an enlightened approach is long overdue. I urge you to do everything possible to allow it to work.

Sincerely,

FOREMAN, ARCH, DODGE

Ref: Draft Environmental Impact Statement for the Anadromous Fish Agreements and Habitat Conservation Plans (HCPs) for the Wells, Rocky Reach and Rock Island Hydroelectric Projects (DEIS)

Dear Mr. Dach:

This letter contains our observations and comments regarding the referenced document. Public Utility District No. 2 of Grant County (Grant PUD) owns and operates the Priest Rapids Hydroelectric Project that consists of the Priest Rapids and Wanapum dams and is geographically situated immediately downstream of the 3 projects that are the subject of this DEIS.

We are generally supportive of the proposed action which, as we understand it, is to issue incidental take permits under Section 10 of the Endangered Species Act to Douglas and Chelan PUDs' based on the HCPs. However, we have a number of concerns with the analysis provided by NMFS in this DEIS and its implications and potential impacts on the Priest Rapids Project. This comment letter will discuss specific concerns regarding the analysis in the DEIS.

GC PUD

1

1. <u>The DEIS Presupposes Consistency of the HCP with the New Federal BiOp and A Non-Existent Basin-Wide Salmonid Protection Programs</u>
The 100 percent no net impact performance standard (NNI) is presented as the centerpiece of the HCPs which are the subjects of the DEIS analysis. However, no scientific justification is given for this standard other than the statement that it is consistent with the performance standards of NMFS' 1995 biological opinion (BiOp) for the Federal Columbia River Power System. In fact, the 1995 BiOp was replaced in 2000. If there is any reason to scrutinize the DEIS in the context of a federal BiOp, the new BiOp should be used for comparison. Furthermore, there is no basis for concluding that the HCPs will be consistent with evolving basin-wide salmon protection plans that do not yet exist (See page 4-39).

2. The Presentation of Vastly Different Alternatives Confuses the Proposed Action

2 Specifically, the DEIS presents separate alternatives relating to Section 7 and Section 10 of the ESA. As we have pointed out in prior correspondence to you, there are substantive and procedural differences between the two Sections that, if glossed over, make it difficult to analyze the impacts of a proposed action and its implications for the various parties to the HCP as well as Grant PUD.

3. The DEIS Presents No Independent Scientific Analysis of the Validity of the NNI Standard

3 At page 4-39, the DEIS states that the NNI standard was developed through negotiations between State and Federal resource agency (sic), PUD, and Tribal biologists. The fact that the NNI standard was negotiated in concert with several parties does not support its scientific validity. We know of no correlation between the NNI standard and the biological needs of listed or non-listed salmonids covered by the HCPs. For example, the DEIS details that the NNI standard is comprised of a 91 percent project survival standard and a 95 percent juvenile dam passage survival standard. The 91 percent project survival standard is derived from an unmeasurable combination of assumptions about dam passage survival of juveniles, reservoir survival of juveniles and the upstream passage survival of returning adults. In addition the HCP relies on assumptions about the efficacy of hatchery supplementation and habitat enhancement projects to achieve the NNI standard. We know of no scientific basis for any of these assumptions. The DEIS acknowledges that many components of the NNI standard cannot be verified (See, page 2-41).

4 We encourage the use of the best available scientific information to support the NNI standard or, in the absence of a verifiable standard, a set of proposed measures which, when analyzed by NMFS, can be shown to meet the requirements of either Section 7 or 10 of the ESA and other applicable law.* A sound means to monitor compliance with the measures and an evaluation system to determine success of the measures are both necessary to prevent the attribution of mortality from these HCP projects to downstream projects.

4. The Water Quality Analysis of the DEIS Is Incomplete.

5 The DEIS states that the mid-Columbia river is on the 303(d) list for exceeding total dissolved gas, water temperature and pH criteria. The DEIS analysis of the alternatives concludes that the preferred alternative is likely to increase total dissolved gas (TDG) levels, with no explanation of how the HCPs would mitigate for these effects or prevent the passage of TDG to downstream projects. Additionally, there is no analysis of how the TDG and temperature impacts would affect fish survival (salmonid and otherwise) within the project areas and downstream. No supporting rationale or analysis is provided as support for the conclusion that the HCPs can be expected to benefit water quality.

* Our understanding of the NNI standard is that it was developed as a negotiated resolution to a variety of regulatory matters and policy issues and goes well beyond what is required for ESA purposes. As such it would not be appropriate or justifiable to apply its standards to other projects.

5. Water Quantity and Socio-Economic Effects Are Not Discussed

The water quantity and socio-economics sections of the DEIS provide no analysis or assessment of the impacts of any of the alternatives under drought conditions or in the
6 event of an energy emergency. As you are aware, the Pacific Northwest is currently experiencing one of the worst water shortages in history. Current projections are that if Columbia Basin runoff declines to 53 million acre-feet as expected, the Pacific Northwest's electricity generators will be unable to meet demand. The proposed action of the DEIS relies on fish spill which exacerbates electricity shortfalls during times of drought or energy emergency. This effect of water quantity shortages and associated socioeconomic impacts should be addressed in the DEIS. Any proposed action should include operational provisions that may be enacted when a declared drought, energy alert or emergency exists.

6. The DEIS Does Not Contain An Adequate Analysis of Impacts on Species Other Than The Four "Plan Species"

7 Four "Plan Species" of salmon are the subjects of the DEIS analysis (See page S-1). The analysis of effects on resident fish species in the Columbia River system concludes that: "Little is known about the effects of project operations on resident fish populations in the Mid-Columbia River" (page 4-27) although it is noted that bull trout have been listed as threatened and are the subject of ongoing consultation and the potential exists for negative impacts on pacific lamprey. The DEIS should be strengthened to reflect available information on the possible effects of the alternatives on other fish species.

7. The DEIS Does Not Meet NEPA Requirements to Consider Cumulative Effects of the Proposed Action

8 The DEIS contains no comprehensive cumulative effects analysis. The only resources evaluated for cumulative effects in this DEIS were listed anadromous salmonids. That analysis was based on an incomplete NMFS analysis that was cited as NMFS (2000c) but not included in the DEIS reference section. In addition, this Quantitative Analytical Report is incomplete, has never received peer review, is not available for public review and any reference to it should be removed and the analysis presented as NMFS' simulations based on a variety of unverifiable assumptions. The analysis presented relies on a subset of available data (1980-94) to conclude that extinction risks are high without presenting information from the full data set analyzed (1960-94) that concludes that extinction risks are actually quite low. The analysis presented also fails to consider recent data showing very large returns of spring chinook. The DEIS fails to include any cumulative effects analysis for summer/fall chinook salmon, sockeye salmon, coho salmon, or any other resource area.

8. The DEIS Does Not Adequately Consider the Impacts of the Proposed Action on Other Agreements Relating to Plan Species

9 The HCPs are intended to support incidental take permits for four permit species including Upper Columbia River summer/fall chinook (page S-1). Fall chinook are protected under the Vernita Bar Settlement Agreement and the Hanford Reach Juvenile Fall Chinook Protection Program. Both Douglas and Chelan PUDs are included in these

programs. However, the DEIS does not analyze the consistency of the HCPs with these other agreements nor does it include an analysis of the obligations of the HCP parties under those agreements.

In conclusion, we reiterate our support for a scientifically supportable HCP and comprehensive DEIS which would justify the issuance of incidental take permits for the permit species. However, for the reasons stated above, we do not believe the DEIS prepared by NMFS adequately provides the necessary science or analysis of the alternatives considered.

Sincerely,

Douglas M. Ancona, Manager
Natural Resources and Regulatory Affairs

Northwest Region Hydro Project
525 NE Oregon Street, #420
Portland, OR 97232-2737

Dear Sirs:

The Greater Wenatchee Community Foundation was formed 15 years ago to provide a new source of funding for worthy organizations. Over the years I have had the privilege of associating with a diverse group of social service and educational organizations. While each pursues individual goals, one thing is also clear; each understands the need to work together with others in the community to develop solutions to problems.

It appears a similar spirit of cooperation is behind the Habitat Conservation Plan developed by the Chelan and Douglas PUDs. As outlined in the plan, the PUDs and regulatory agencies work cooperatively to find and implement the best methods for ensuring fish survival. The plan also includes provisions for timely resolution of any disputes. It sets up an oversight committee for coordination and consultation between the PUDs and interested parties and agencies.

The PUDs are a key ingredient in the economic vitality of the Greater Wenatchee area. The plan they are proposing holds the key ingredients to their success, and to ensuring continued economic operation of the public utilities.

While it is important that endangered salmon be saved, it is also important to invest in the most cost-effective, scientifically sound solutions. The plan ensures that the PUDs will do their part to save salmon, while providing for long-term, affordable hydropower for local residents.

I urge you to favorably consider the Habitat Conservation Plan of the two PUDs and to move it forward as quickly as possible.

Sincerely yours,

G. Raymond Taylor
President and CEO

Re: Chelan and Douglas County's Draft Environmental Impact Statement (DEIS) for fish conservation.

Gentlemen:

We appreciate the time and resources the Chelan and Douglas County Public Utility Districts (PUDs), tribes, and agencies spent developing the DEIS and also appreciate the opportunity to comment.

The PUDs want, among other things, to ensure the production of hydroelectric power will not be disrupted by changing requirements for anadromous fish. They want this certainty to last for 50 years. We would like to see fish populations increase with the hope that listed species will be removed from threatened or endangered lists and that other fish species will continue to flourish as well.

The Public Utility Districts indicate in the DEIS that they prefer Alternative three. For the following reasons, we equally prefer Alternative three:

1. Citizens at the local level have an opportunity to be involved through the habitat improvement programs.
2. Alternative 3 promotes an ongoing action separated from the swings of political forces to recover listed fish species while at the same time assuring a measure of protection for other fish species as well.
3. The preferred alternative provides certainty for both the PUDs goal of producing electricity and certainty for those of us who regard fish in our streams as one of the indicators of continued prosperity.

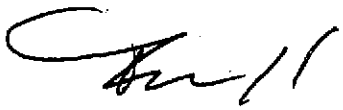
IC

1 We agree with the concerns National Marine Fisheries Service has about the seven per cent hatchery compensation levels and how they may adversely affect wild salmon populations. We recommend that the PUD guarantee in writing that only native stock will be produced under the seven per cent hatchery compensation program and that hatchery management protocol will ensure the genetic integrity of wild fish.

2 We were disappointed to read that such a small portion of the nine percent compensation was given over to habitat improvements. We understand the difficulty in quantifying the results of habitat improvements. Nevertheless, at the heart of declining fish populations, is loss of habitat. We would have preferred four per cent of the compensation given to habitat improvements instead of two per cent with less emphasis on hatchery production.

3 Finally, we would like to see assurance that the majority of funds for habitat improvement and restoration be spent in the first part of the 50-year agreement. The sooner habitat improvements are completed, the sooner the results can be monitored.

Sincerely,



Buford Howell,
President

February 7, 2001

Gentlemen:

As a longtime businessman in Chelan County and a Lake Chelan Valley resident, I am writing to add my support for the mid-Columbia Habitat Conservation Plan (HCP).

From my perspective, Chelan County businesses, farms and industries are feeling the squeeze of intense regulatory burdens. Often the regulations come in the form of mandates from agencies that know very little about the issues of our area and are unapproachable about unique, local solutions.

The HCP provides Chelan County PUD the opportunity to design programs and systems to meet agreed-upon survival standards for its Columbia River dams. The PUD knows the business of running its dams better than anybody else. Giving the PUD the opportunity to design and implement fish protection measures, rather than respond to agency-driven mandates, makes good sense to me.

Another item that I particularly like is the "no net impact" standard. If the PUD achieves the survival standards at its hydroelectric projects, it provides supplementation hatchery capacity and habitat funding to make up for unavoidable losses. The end result is the certainty that we can relicense Rocky Reach Dam and continue to provide reliable, reasonably-priced electricity to our customer-owners.

It is also important to note that Chelan PUD has not been idly standing by waiting for the HCP to go through the long regulatory process. As an example, the PUD has thoroughly tested a prototype state-of-the-art bypass system at Rocky Reach and will begin a permanent installation in 2001.

While many of us in Chelan County may not agree with the requirements of the Endangered Species Act, it appears that we have little choice but to comply with the law. What we need is a reasonable template to work from that allows for common sense and local solutions in achieving survival standards. This HCP seems to meet that mark. Let's stop wasting time and get it done.

Sincerely,

David Gellatly

Portland, OR 97232-2737

To Whom It May Concern:

Our firm has been in business for 45 years, serving the residents of North Central Washington. The economic situation for our area is very precarious and uncertain for the future. For the past several years, I have watched countless regulations pile up on the citizens of Chelan County. Many of the continued mandates are produced by out-of-town bureaucrats without a regard for our local citizens and our way of life. Our area is now to the point where many orchardists are either ripping out their fruit trees and/or facing bankruptcy. Water regulations are stifling growth in other areas. Housing starts are down and living wage jobs are hard to come by. The future of the Alcoa plant in Wenatchee is in question. All of these things have certainly had an impact on our family-owned business and those of my friends and neighbors.

In these difficult times, one of the blessings we have been able to count on is relatively low-priced, dependable electricity from our citizen-owned public utility district. The PUD has certainly faced its' challenges in dealing with costly mandates as well. Re-licensing the dams, expensive fish programs and many other items have steadily increased rates, although fortunately not nearly as much as in other areas that have to rely upon coal, nuclear power and other more expensive forms of electric generation.

Eastern Washington has not experienced the dynamic economic growth that Western Washington has achieved. People in our area are also very concerned that somehow California will be able to siphon off our power further jeopardizing our area's economy. We must keep our hydroelectric dams providing reasonably priced power if our communities are to have a chance to grow and prosper. That is why I am voicing my support in this letter for the habitat conservation plan for our PUD's dams on the Columbia River.

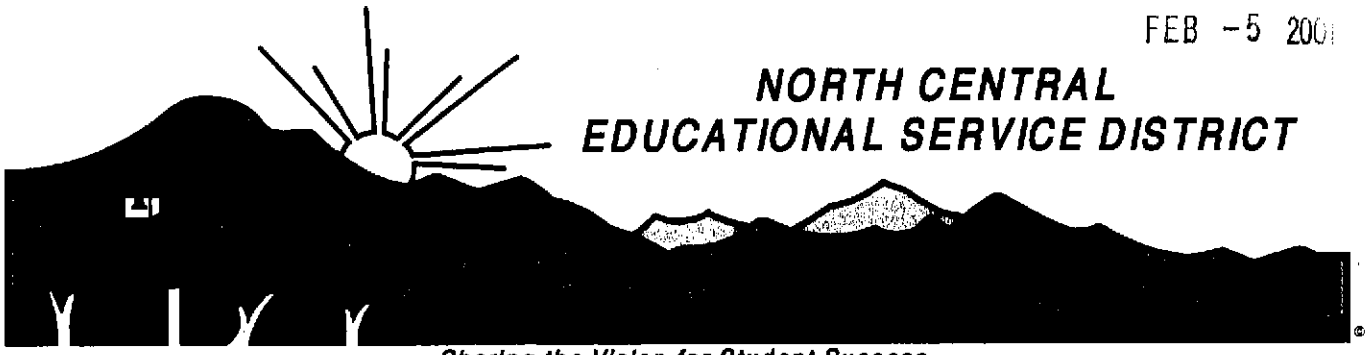
Although I do not know every detail about the HCP, it is my understanding that it addresses the ESA mandates. I support the idea of outcome-based survival standards as opposed to simply ordering the PUD to take expensive actions to protect the fish with no accountability from outside agencies. Having the PUD establish and implement cost-effective, scientifically-based programs that are unique to our dams gives us the opportunity to protect our local power generation while doing what is right for the fish. If we do our part, the dams are protected from removal and re-licensing is assured. That makes good sense.

From my point of view, it seems as though all of these various government agencies, Indian tribes and other parties can rarely agree on anything. We have wasted tens of millions of dollars spending money on fish programs that represented somebody's best guess on solving the problem. The HCP appears to be the exception. Although for some reason, this program took over five years to negotiate. It has taken even longer to wade through the regulations. I noted that some pretty diverse groups, like American Rivers, National Marine Fisheries, Indian tribes and others signed the declaration stating that the HCP is a good idea. Now, maybe we finally have a program we can all support.

Without further delay, please keep the HCP moving forward. We need this program to protect our dams, to meet the ESA mandates and to keep our communities growing and surviving.

Sincerely,

Ken Marson, Jr.
President



January 29, 2001

National Marine Fisheries Service
Northwest Region – Hydro Program
525 N.E. Oregon Street, Suite 420
Portland, OR 97232-2737

To Whom It May Concern:

During my nine years of service as the superintendent of the North Central Educational Service District 171, I have had the pleasure to work with the Chelan County PUD on many successful projects.

In the field of education, the PUD has been a leader in the development of a four-county educational cooperative that provides high-quality, well-respected curriculum from kindergarten through middle school.

Chelan County PUD has also proven to be an outstanding partner in several other successful community education projects, including bringing distance learning to Wenatchee Valley College, helping to develop the North Central Technical Skills Center and developing a Technology Center in the Olds Station Industrial Area.

In my role as both an educator and an avid recreationist, I have noted the PUD's role in yet another collaborative venture – the development of a comprehensive Habitat Conservation Plan (HCP) for the mid-Columbia area. For the record, I wholeheartedly endorse this program.

The HCP demonstrates to our community, from students to business leaders, that parties with diverse interests can work together to develop common-sense programs that address our hydroelectric energy requirements while protecting our valuable fisheries resources.

All too often regulatory agencies seem determined to mandate specific measures, evaluate their success and add on still more measures. We then end up with an endless cycle of more regulation. Under that scenario, the focus on results is lost, millions of dollars are wasted and court battles are the only recourse.

The HCP challenges that trend. With survival standards as the goal, all parties work cooperatively on the development of solutions. Testing ensures results. Unavoidable losses are compensated through a unique balance of natural hatchery production and habitat enhancements.

Endangered Species Act requirements are met while protecting our low-cost hydropower resources that benefit not just our local citizens, but also millions of citizens throughout Washington and the Northwest.

I urge your continued resolve to move the HCP swiftly through the regulatory process. Citizens are anxiously awaiting a national model for cooperatively addressing both our energy and environmental needs. This appears to be it.

Sincerely,

Gene Sharratt

Mr. Dick Nason
PUD No. 1 of Chelan County
P.O. Box 1231
Wenatchee, WA 98807-1231

Dear Mr. Nason,

The Northwest Power Planning Council appreciates the opportunity to comment on the Habitat Conservation Plan to protect and enhance salmon and steelhead in the Mid-Columbia River. We commend you for sticking with the development of this document, six years in the making.

It is the Council's understanding that a collaborative effort involving a group with diverse interests has worked to develop this Habitat Conservation Plan. Chelan and Douglas PUD's, the National Marine Fisheries Service, the U.S. Fish and Wildlife Service, the Washington Department of Fish and Wildlife, the Yakama, Colville, and Umatilla Tribes, American Rivers, Inc, and major purchasers of wholesale energy are some of the partners identified as participating in this endeavor. The Council supports the development of these negotiated agreements.

In the next couple of years, the Council will be embarking on a subbasin planning process, and will be working to bring parties with diverse interests together to protect, mitigate, and enhance fish and wildlife harmed by the operation of the hydropower system. Your demonstrated commitment to fish and wildlife will be instrumental in assisting the Council to successfully develop a broad-based plan for the Mid-Columbia.

The Northwest Power Planning Council understands that Chelan County PUD is firmly committed to this Habitat Conservation Plan. We continue to wish you success in your endeavor, and appreciate the hard work you have put in to develop this negotiated agreement.

Regards,

Frank L. Cassidy, Jr., Chairman
Northwest Power Planning Council

RE: Comments on DEIS for Wells, Rocky Reach, and Rock Island Hydro Projects

Thank you for allowing the public to comment on future operations of the Mid-Columbia Hydro projects as to their impacts on the fishery resource. The DEIS is very general and is lacking in what it doesn't say rather than what it says. The following comments are directed mostly to habitat considerations rather than dam operations.

OWL

Consistency

1 The Okanogan Wilderness League (OWL) has followed the Mid-Columbia process since the late 1980's and has commented on the different protocols that have been developed for spring chinook recovery in the Methow Basin. I am including two of our comments as enclosures that point out some of the inconsistencies and deviations from the adopted FERC Settlement Agreements. The FERC agreement identifies three separate spring chinook populations in the Methow Basin and the DEIS identifies the spring chinook as "composite" stock. The escapement of wild fish for natural spawning is not consistent with previous protocols.

Fish flow

2 The DEIS recognizes that in-steam flow is a habitat consideration in its analysis of tributaries such as the Wenatchee and the Methow, but fails to analyze fish flows for the Columbia River.

Fish management must be flexible enough to change. It should not be held hostage in committees that have veto power for change. This is especially important when that veto power is held by the PUDs who have an economic vested interest detrimental to the best interest of fish. The HCP(alt 3) runs for 50 years and recognizing the above considerations, is not in the best interest of the fisheries resource. Because of the flexibility in the consultation process the only acceptable alternative in the DEIS is alternative 2.

Sincerely;

encl: 2

PACIFIC AEROSPACE & ELECTRONICS, INC.

February 13, 2001

National Marine Fisheries Service
Northwest Region – Hydro Program
525 N.E. Oregon Street, Suite 420
Portland, OR 97232-2737

On behalf of Pacific Aerospace & Electronics, Inc. (PAE), I am writing to support the mid-Columbia Habitat Conservation Plan (HCP).

PAE employs over 450 people in Chelan County. Our company designs, manufactures and sells components and subassemblies used in technically demanding environments. Affordable, reliable electricity is a critical element of our bottom line. We simply cannot tolerate major price increases and/or interruptions in electric service and remain competitive.

With the energy crisis in California and the Northwest, it is apparent that we maximize all of our existing generation, especially the clean, renewable hydropower dams that fuel this region. Further, new power plants must be built immediately.

From my perspective, it appears that the HCP preserves affordable, reliable hydropower for our business and our communities while meeting federal and state requirements to protect the Columbia River fish.

The HCP offers the Chelan and Douglas PUDs an opportunity to seek cost-effective fish protection methods that are unique to the individual dams, as opposed to seemingly endless fish protection mandates from outside agencies. Mandates without accountability equals waste, and quite frankly that is exactly what we have been seeing from regulatory agencies in the past.

Please add our voice to the public record in support of the HCP.

Sincerely,

Don A. Wright
President & CEO

PNUCC

Bringing the *Power* of good ideas *Together*

April 4, 2001

Ms. Donna Darm
National Marine Fisheries Service
Northwest Region - Hydro Program
525 N.E. Oregon St., Suite 420
Portland, OR 97232-2737

Dear Donna:

The Pacific Northwest Utilities Conference Committee (PNUCC) has played an important role in the region's electric utility industry for over 50 years. As a voluntary, non-profit organization, PNUCC is a forum for bringing the power of good ideas to bear on a range of issues including the recovery of ESA listed salmon.

PNUCC has been engaged in the salmon issue for many years seeking a regional plan that will successfully recover endangered salmon. In order for a plan to succeed it must address the salmon's entire lifecycle; have clear, consistent goals; clearly articulate who is accountable for meeting the goals; and be acceptable by all interested parties. Such a regional plan would provide a guide for local actions for fish. In addition, the regional plan would be used to assure that individual actions at the local level are consistent with the region's goals and are complementary and not at cross-purposes.

The mid-Columbia Habitat Conservation Plan (HCP) is consistent with our regional goals and we ask that NMFS fully endorse it. The HCP successfully meshes fish management with hydropower operations and it embodies many key principles PNUCC strongly supports for recovering salmon in the Pacific Northwest. It establishes overall survival targets for fish. It is comprehensive in nature, relying on habitat improvements and hatchery operations, as well as, hydro operations to improve fish survival. It relies on the innovations of the project owners, giving them the responsibility and accountability for meeting fish survival targets yet provides for oversight from and cooperation with interested agencies and parties. And most importantly, the mid-Columbia HCP is the product of a comprehensive, collaborative process that included all the major stakeholders. We see this as a successful formula that recognizes the unique characteristics of each hydroproject.

In order to maintain system reliability and ensure a stable power supply for the Northwest, it is imperative that the region has certainty to the amount of power available from the NW hydropower system. The HCP provides some additional certainty for the operation of the three dams it addresses and thus their power contributions.

This HCP is one example of how to locally and effectively address salmon recovery. We urge you to adopt the principles of the HCP and move forward on meeting its admirable goals.

Sincerely,

David E. Piper

National Marine Fisheries Service
Northwest Region – Hydro Program
525 N.E. Oregon Street, Suite 420
Portland, OR 97232-2737

Dear Sirs:

Please consider this a strong endorsement of the Habitat Conservation Plan (HCP) for Chelan and Douglas PUDs now under review by your agency.

Agriculture – long the lifeblood of North Central Washington – is hurting. Thousands of fruit trees are being ripped out as growers give up and file for bankruptcy. Agriculture's plight is having a ripple effect throughout our communities, and we are in the midst of a serious economic downturn.

But so far, we can still count on reliable, low-cost energy. It remains a pillar of our past and a key foundation to building our future. We must have ample water to irrigate our remaining and future orchards. We need low-cost power to pump that water to the orchards, to run the packing lines where we process our fruit, and to power the controlled-atmosphere storage that maintains pears, apples and other produce in quality marketing condition. With so many other forces squeezing agriculture, the Habitat Conservation Plan can help by providing more long-term certainty regarding water supplies and electric power.

The Habitat Conservation Plan assures the PUDs of guidelines under which they can operate most effectively and efficiently. It provides a framework for fish mitigation with identifiable targets. The plan lets the local experts direct operations, but with federal and state oversight. It offers a common-sense approach that is good for fish and good for our region.

Our PUDs have done a great job caring for our local resources. The Habitat Conservation Plan demonstrates responsible stewardship. We can help fish and help people too, by ensuring the continued production of reliable hydropower for the citizens of the northwest.

Thank you,

Dan Gaspar

RE: Habitat Conservation Plans Proposed by Chelan and Douglas PUDs

Dear Mr. Dach:

I am writing on behalf of Pacific Northwest Generating Cooperative (PNGC Power) to express support for the Habitat Conservation Plans (HCPs) for the Wells, Rocky Reach and Rock Island Hydroelectric Projects that are currently the subject of a Draft Environmental Impact Statement that is out for public comment. PNGC Power is an energy services cooperative owned by 15 rural electric cooperatives throughout the Northwest. We have a strong interest in plans that effectively protect natural resources while taking into account the serious needs of the rural economy in the Northwest.

There are several aspects to these HCPs that make them worthy of your approval. In fact, these same aspects make these HCPs models that will serve the region well during discussion over other species recovery efforts. First, the emphasis on setting specific outcome-based targets will prove extremely useful during implementation, monitoring, and review of the plans. Proper focus is put upon real results regarding the species themselves, rather than upon fulfilling a checklist of measures that may or may not be effective.

Second, the balance within these plans is very evident and is another key towards creating a viable, enforceable approach. Especially in light of the current predicament in the West Coast energy market, the balancing of species protection and recovery with the need to preserve a reliable supply of energy is crucial for the economic health of the region.

Finally, the level of collaboration evidenced by the diverse array of supporters for these plans is very impressive. As we have seen in many other natural resource proceedings this type of broad collaboration is very difficult to achieve and is to be commended.

In summary, these HCPs form a balanced approach to addressing some very challenging issues. Their unique proposals for creating scientific and economic accountability in species recovery should serve the region well. We ask that you adopt the principles included in these HCPs.

Sincerely,

Scott Corwin
Manager, Government Affairs

Mr. Bob Dach
Hydro Division
National Marine Fisheries Service
525 NE Oregon Street.
Portland, OR 97232-2737

Dear Mr. Dach:

The Public Power Council (PPC) is a trade association of consumer-owned electric utilities in six states here in the Pacific Northwest. We applaud NMFS, Douglas and Chelan PUDs for their efforts to develop long-term habitat conservation plans for the Wells, Rocky Reach and Rock Island Hydroelectric Projects.

The proposed Anadromous Fish Agreement and Habitat Conservation Plans (HCP) are particularly timely given the Northwest's present short supply of renewable electric energy. Our region is now struggling to maintain its economic vitality in light of recent developments in the wholesale power market. Solutions to these issues must be found through active planning and long-term solutions. The proposed HCP represents both of these ideals.

We support the proposed Wells, Rocky Reach and Rock Island HCPs as the preferred alternatives for salmon protection, mitigation and enhancement at those hydroprojects. The selection of the long-term HCPs is intended to ensure the future viability of anadromous salmonids while maintaining the benefits of clean, renewable hydroelectric power generation. We encourage NMFS to select and implement Alternative 3 as described in the Draft Environment Impact Statement for the proposed Wells, Rocky Reach and Rock Island Anadromous Fish Agreements and HCPs.

Sincerely,

C. Clark Leone
Manager

Re: Draft Environmental Impact Statement: Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects

Dear Mr. Dach:

The Save Our *Wild* Salmon Coalition, National Wildlife Federation, Friends of the Earth, Cascade Chapter of the Sierra Club, Northwest Sportfishing Industry Association, Pacific Coast Federation of Fishermen's Associations, and Institute for Fisheries Resources appreciate the opportunity to comment on the draft Environmental Impact Statement (DEIS) for the proposed Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects, dated November 2000. We have reviewed the document and offer the following comments.

SOWS

The hydropower projects at issue have played a significant role in the decline of anadromous fish populations in the Columbia River basin, several of which are now listed under the Endangered Species Act. Any alternative for continued operations of the projects must promote recovery of these stocks and ensure that such operations do not jeopardize their continued existence. The proposed Habitat Conservation Plan purports to be a comprehensive agreement to promote actions that will improve conditions and lead to the recovery of species. However, based on the limited analysis contained in the DEIS, we believe it would be imprudent for the National Marine Fisheries Service to move forward with the proposed Habitat Conservation Plans (HCPs). Due to the lack of legal and scientific analyses of any of the alternatives in the DEIS, we cannot support any of the alternatives at this time. Section 7 of the Endangered Species Act requires NMFS to consult with the Federal Energy Regulatory Commission over the operation of these projects immediately. Anything less than this, such as the alternatives discussed in this DEIS, does not comply with the law. We are deeply troubled by this blatant lack of compliance with federal law and policy and urge you to reconsider your approach to satisfying your responsibilities under the National Environmental Policy Act (NEPA), the Endangered Species Act (ESA), the Clean Water Act (CWA), and the Federal Power Act (FPA).

1

National Environmental Policy Act

1. The DEIS fails to take a "hard look" at all of the environmental information and consequences of each alternative.

2

The fundamental purposes of NEPA are to guarantee that: (1) federal agencies take a "hard look" at the consequences of their actions before the actions occur by ensuring "that the agency, in reaching its decision, will have available, and will carefully consider, detailed information concerning significant environmental impacts," *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 349 (1989); and (2) "the relevant information will be made available to the larger audience that may also play a role in both the decisionmaking process and the implementation of that decision," *id.* at 349. In short, NEPA requires federal agencies to look before they leap. This DEIS fails to serve this critical function.

To satisfy the requirement that it take a "hard look" at the environmental consequences of its actions, an agency must engage in a "reasoned evaluation of the relevant factors" to ensure that its ultimate decision is truly informed, *Greenpeace Action v. Franklin*, 14 F.3d 1324, 1332 (9th Cir. 1992). The DEIS must be searching, detailed and comprehensive; "[g]eneral statements about 'possible' effects and 'some risk,' do not constitute a 'hard look' absent a justification for why more definitive information could not be provided," *Neighbors of Cuddy Mountain v. United States Forest Service*, 137 F.3d 1372, 1380 (9th Cir. 1998).

An agency's failure to include and analyze information that is important, significant, or essential renders an EIS inadequate – for, without such detailed information, there is no way for the public or the agency to adequately assess the impacts of a proposed action. *See California v. Bergland*, 483 F. Supp. 465, 495 (E.D. Cal. 1980), *aff'd sub nom, , California v. Block*, 690 F.2d 753 (9th Cir. 1982) (by failing to disclose key data, "the Forest Service effectively undercut the twin goals of environmental statements: informed decisionmaking, and full disclosure").

NMFS may not, as it has done throughout this DEIS, ignore relevant information and rely upon conclusory statements and unsupported assertions to satisfy NEPA's "hard look" requirement. We believe that these deficiencies present an inaccurate picture of the impacts to the public, making it impossible for anyone, including NMFS, to draw any reasoned conclusions about the environmental impacts of the three alternatives presented in this DEIS.

For example, the HCPs (Alternative 3) rely on "off-site" habitat improvements and hatchery supplementation to make up for 2% and 7%, respectively, of the 9% "unavoidable" mortality caused by these projects. As a threshold matter, NMFS fails to justify or explain this 2/7% division and provides no explanation for how it will measure these needed improvements. *See infra* at 14-15. Compounding this omission, the DEIS contains no explanation for whether the funds to implement these measures will be adequate to achieve the benefits necessary to mitigate for this mortality. The DEIS does not even attempt to connect the funding proposed for Alternative 3 with the actions to be taken as part of the HCPs. Not surprisingly, since the DEIS contains no explanation of what these measures may be, or how/when they will be funded or implemented, NMFS presents no data or scientific analysis whatsoever to explain how the benefits will accrue. The best the DEIS can do is to acknowledge that "there is considerable difficulty measuring the effectiveness of habitat improvement projects, [but] there are numerous areas with degraded habitat in the Mid-Columbia River tributaries that would benefit from improvement or plan protection programs." DEIS at 4-41. This may well be the case, but this conclusory statement does not approach the level of analysis required to allow the public or a decisionmaker to conclude that Alternative 3 will actually provide the survival benefits necessary to mitigate for the effects of the PUD's actions, nor does it present enough information to support NMFS' threshold conclusion that it will result in a quantifiable increase in survival. Such generalized and speculative statements about hoped-for benefits

do not satisfy NEPA's "hard look" requirement. "A mere listing of mitigation measures is insufficient to qualify as the reasoned discussion required by NEPA." *Neighbors of Cuddy Mountain*, 137 F.3d at 1380. Courts routinely reject such vague discussions of mitigation measures where, as here, they "are so general that it would be impossible to determine where, how, and when they would be used and how effective they would be." *Id.* at 1381.

2. The DEIS fails to analyze the cumulative impacts of myriad other actions that affect Middle and Upper River Columbia salmon and steelhead.

3

Perhaps the most glaring omission in the DEIS is NMFS' failure to consider cumulative impacts in its analysis. To ensure that the combined effects of separate activities do not escape consideration, NEPA requires that federal agencies consider cumulative environmental impacts in their environmental analyses. Cumulative impacts result "from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." 40 C.F.R. § 1508.7

NEPA requires a cumulative impacts analysis to: (1) catalogue past projects in the area; (2) assess the cumulative environmental impacts of those projects with the proposed project; and (3) analyze the additive cumulative impact of all reasonably foreseeable Federal and non-Federal actions, whether or not they have actually been proposed. *See City of Carmel-By-The-Sea v. United States Dep't of Transp.*, 123 F.3d 1142, 1160 (9th Cir. 1997) (rejecting cumulative impacts analysis that referred generally to other past "development projects" and did not discuss the additive impacts of foreseeable future projects); *Fritiofson v. Alexander*, 772 F.2d 1225, 1243 (5th Cir. 1985) (agency must consider reasonably foreseeable actions regardless of whether they have yet formally been proposed). Furthermore, NEPA requires that a cumulative impacts analysis provide "some quantified or detailed information" because "[w]ithout such information, neither courts nor the public . . . can be assured that the Forest Service provided the hard look that it is required to provide." *Cuddy Mountain*, 137 F.3d at 1379.

The DEIS falls far short of satisfying a single one of these requirements. For example, the DEIS ignores even the impacts of other dams in the Columbia River. Most notably, the DEIS contains no analysis of the cumulative impacts of these alternatives when combined with the Grant County PUD's Priest Rapids and Wanapum dams, located just downstream of those covered by the HCPs analyzed in Alternative 3. Nor is there any mention of the cumulative effects of hydro operations on the Middle or Upper Columbia River tributaries, such as the Yakima and Chelan rivers. These tributaries house numerous hydro and diversion projects and irrigation withdrawals that have a significant impact on these same listed Middle and Upper Columbia River stocks. In addition, the U.S. Army Corps of Engineers has recently analyzed a proposal to deepen the Lower Columbia River – an action that, if approved, will impact Middle and Upper Columbia River juvenile and adult salmon and steelhead as they migrate through the lowest reach of the Columbia River estuary. This dredging project – while currently awaiting a Record of Decision – has been analyzed in a Final EIS and is therefore clearly "reasonably foreseeable," but there is no mention of it in the DEIS.

These examples are by no means exclusive. There are myriad other, easily identifiable actions and conditions that impact the Middle and Upper Columbia stocks, including, but not limited to, continuing habitat destruction and modification from on-going and proposed land-management activities, such as timber sales and livestock grazing on both public and private lands and the operation of the FCRPS. All of these activities and factors – whether they be in the development stage, or completed projects – must be catalogued and considered in NMFS' cumulative effects analysis.

Nowhere, however, does the DEIS meaningfully discuss the cumulative impacts of any these activities. Although NMFS alludes to its "Quantitative Analytical Report" (QAR) purportedly used to identify cumulative effects, it fails to employ or explain this model, drawing only the most general conclusions about the impacts of actions in other life stages in conjunction with each alternative. *See, e.g.*, DEIS at 4-44 ("The protection and enhancement of riparian habitat ... are expected to result in increased natural production levels for both anadromous and resident fish species."). Such conclusory and generalized statements do not satisfy the requirement that NMFS take a "hard look" at cumulative impacts.

The DEIS compounds these errors by painting an optimistic outlook for the Middle and Upper Columbia's listed stocks. *See, e.g.*, DEIS at 4-4 to 4-16. NMFS' discussion of these other actions takes full advantage of the potential positive effects of actions, but fails to account for – or even mention – any of the actions that may have negative impacts. Looking at only the positive side of the ledger distorts the true picture of the effects of the action to the public and inflates the already speculative benefits of many of these actions. NEPA's cumulative effects requirement demands that NMFS complete a comprehensive analysis that includes all of the actions occurring in the basin.

NEPA "emphasize[s] the importance of coherent and comprehensive up-front environmental analysis to ensure informed decision making to the end that 'the agency will not act on incomplete information, only to regret its decision after it is too late to correct.'" *Blue Mountains Biodiversity Project v. Blackwood*, 161 F.3d 1208, 1216 (9th Cir. 1998). The DEIS' terse and incomplete discussion of cumulative effects fails to satisfy this fundamental requirement. The DEIS' failure to analyze all past, present, and reasonably foreseeable future actions results in a skewed, and ultimately inaccurate picture of the impacts of the proposed actions, leading to the kind of "blinders-on" decision-making that NEPA is designed to prevent.

3. The DEIS Fails To Consider an Adequate Range Of Alternatives

NEPA, §101(2)(C)(iii), requires that an EIS contain a discussion of the "alternatives to the proposed action." The discussion of alternatives is at "the heart" of the NEPA process. 40 C.F.R. §1502.14. The CEQ regulations require the agency to "[r]igorously explore and objectively evaluate all reasonable alternatives." 40 C.F.R. §1502.14(a). All federal agencies shall, to the fullest extent possible, "[s]tudy, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources." 42 U.S.C. § 4322(2)(E); *Idaho Conservation League v. Mumma*, 956 F.2d 1508, 1519-20 (9th Cir. 1992). A federal agency must look at every reasonable alternative within the "nature and scope of the proposed action," *California v. Block*, 690 F.2d 753, 761 (9th Cir. 1982), "sufficient to permit a reasoned choice." *Methow Valley Citizens Council v. Regional Forester*, 833 F.2d 810, 815 (9th Cir. 1987), *rev'd on other grounds sub nom. Robertson v. Methow Valley Citizens Council*, 490 U.S. 332 (1989). The failure to consider all reasonable alternatives is fatal to the adequacy of an agency's NEPA analysis. *Idaho Conservation League*, 956 F.2d at 1519 ("The existence of a viable, but unexamined alternative renders an environmental impact statement inadequate."). The DEIS is deficient in many respects with regard to the alternatives considered.

4

First, according to the Habitat Conservation Planning Handbook, the "no action" alternative "means that no permit would be issued and take would be avoided or that the project would not be constructed or implemented." Handbook at 3-35. The "no action" alternative presented in the DEIS does neither. Indeed, the "no action" alternative is really not an alternative at all because, as NMFS admits, it would violate the ESA and leave both the Federal Energy Regulatory Commission ("FERC") and the PUDs liable for causing a "take" of listed species. DEIS at 1-14 (only the "action alternatives ... will provide FERC and the PUDs legal coverage from the take prohibitions under section 9 of the act."). In short, Alternative 1 fails to present any alternative at all.

NMFS should evaluate a true "no action" alternative that considers "no project" conditions to fully assess the impacts of issuing incidental take permits for the Rocky Reach, Rock Island, and Wells hydroelectric projects. The reason for analyzing river conditions without the project is not just to consider past impacts, but to open up the full range of alternatives and impacts associated with a decision to continue the project. Understanding environmental conditions that would exist without a project is essential to evaluating the ongoing impacts of the projects and discerning key ecological components of a healthy aquatic ecosystem. Only by considering a no-project alternative can NMFS "explore all issues relevant to the public interest, including future power demand and supply, alternative sources of power, the public interest in preserving reaches of wild rivers and wilderness areas, the preservation of anadromous fish for commercial and recreational purposes, and the protection of wildlife." *LaFlamme v. FERC*, 852 F.2d 389, 402 (9th Cir. 1988) (quotation omitted).

4

As Courts have explained:

> [t]he goal of [NEPA] is to ensure that federal agencies infuse in project planning a thorough consideration of environmental values. The consideration of alternatives requirement furthers that goal by guaranteeing that agency decisionmakers have before them and take into proper account all possible approaches to a particular project (including total abandonment of the project) which would alter the environmental impact and cost-benefit balance. ... Informed and meaningful consideration of alternatives – including the no action alternative – is thus an integral part of the statutory scheme.

Bob Marshall Alliance, 852 F.2d at 1228 (citations and quotations omitted; emphasis in original).

The DEIS gives short shrift to considering this true "no action" alternative. Instead, NMFS states that, due to perceived legal and timing constraints, "dam removal is not considered a reasonable alternative." If the baseline against which all alternatives are judged is the present state of the hydropower project, there can be no way to evaluate the pluses and minuses of rejecting or substantially modifying those operations. Without collecting and disclosing the costs and benefits of such options, the informed decisionmaking and full public disclosure purposes of NEPA cannot be met.

Whether better characterized as a "no-action" or an action alternative, NEPA requires NMFS to give full consideration to alternatives that include not proceeding with the activities. NMFS must analyze the condition of the river without the project and outline the public benefits gained from restoring the river to a more natural state. Both these inquiries are necessary for NMFS to fulfill its NEPA obligations.

Second, stripping away the alternatives given only brief consideration and eliminated in the EIS, and the "no action" alternative – which violates the ESA – NMFS is left with only two alternatives. Such a narrow range of alternatives does not fulfill NEPA's mandate to rigorously explore alternatives. For example, the Court in *Commonwealth of Massachusetts v. Clark*, 594 F. Supp. 1373 (D. Mass. 1984), found that the Department of Interior had not considered an adequate range of alternatives in its analysis of an offshore oil drilling proposal. Of the thirteen alternatives presented in the document, the court found that, "once the illegal and overlapping alternatives are removed from the FEIS, the Secretary was presented with basically only two different configurations for the sale... the FEIS is hopelessly skewed in favor of only small deletions from the propos[ed action]." Id. at 1380.

The DEIS' failure to consider a reasonable range of alternatives is even more troubling in light of the fact that many alternatives clearly exist. Notably, the DEIS fails to consider any alternative that would be more protective of fish, such as drawdown, non-power operations, or the installation of sluiceways at each

project. While such alternatives may cost more, the DEIS presents no information for the decision-maker or the public to draw any conclusion about the benefits, or cost of such a measure.[1]

Finally, the DEIS relies on inaccurate information in its comparative analysis of alternatives. The DEIS emphasizes repeatedly that Alternative 2 will take longer to implement due to the potential for legal challenges from the PUDs. See, e.g., DEIS at s-32, 1-15, 2-53, 4-6. This fear, however, is nothing more than a straw man of NMFS' own construction. First, while it is true that the PUDs may prefer the less stringent measures that would result from Alternative 3, it is irrational to make the leap from that to a delay. The section 7 consultation with FERC described in Alternative 2 will yield the measures necessary to avoid jeopardy and will provide incidental take coverage for FERC and, by proxy, the PUDs. Even if either entity challenges these measures, they must still adhere to the results of consultation during that challenge, or they would be liable for a take under section 9 of the ESA. 16 U.S.C. § 1538. Thus even if, as NMFS assumes, one of the actors challenges the results of consultation, the measures required must still be implemented immediately to avoid take liability. The DEIS fails to disclose and to account for this fact in its analysis.

4. The DEIS fails to adequately inform the public and decision-makers of the requirements and responsibilities of all federal statutes and treaties.

5

"A reasoned evaluation of the relevant factors" must also include an understanding of all the federal laws with which an agency must comply, especially when those other laws have been enacted to protect environmental and natural resources. In this case, the DEIS fails to inform adequately the public and the decision-makers of the requirements under numerous other laws including, but not limited to the Endangered Species Act ("ESA"), 16 U.S.C. §§1531 *et seq.*, and the relationship between the alternatives and the requirements of these laws and treaties. To give the public and decision-makers the tools necessary to balance all relevant factors, the DEIS must address the basic requirements of these statutes.

For example, the DEIS states that Alternative 3 is intended to meet the requirements of the Federal Power Act and purports to analyze this requirement. Indeed, the DEIS implies that Alternative 3 is the only alternative that meets the requirements of the FPA. The DEIS does not, however, disclose that other alternatives must also comply with the FPA. By failing to disclose and analyze this requirement for the other alternatives, the DEIS presents the public and the decisionmaker with an inflated and inaccurate picture of the benefits of Alternative 3.

Endangered Species Act

NMFS' analysis in the DEIS is wholly insufficient to comply with the underlying legal obligations of the Endangered Species Act (ESA), 16 U.S.C. §§ 1531 *et seq.* The ESA is the "most comprehensive legislation for the preservation of endangered species ever enacted by any nation." *TVA v. Hill*, 437 U.S. 153, 180 (1978). "[T]he language, history, and structure of the legislation . . . indicate[] beyond a doubt that Congress intended endangered species to be afforded the highest of priorities." *TVA*, 437 U.S. at 174.

[1] The DEIS states that the "purpose of the HCPs is to protect fish in the Mid-Columbia River while generating electricity." DEIS at 1-3. This statement too narrowly cabins the rest of the analysis by removing, among other things, consideration of a true "no action" alternative. Moreover, it assumes that the HCPs analyzed in Alternative 3 are the proper means to comply with the ESA. We believe that the purpose and need must be expanded to emphasize protection of listed species and compliance with the requirements of the Endangered Species Act. The HCPs are only a proposal to meet the requirements of the ESA, they are not an end in themselves. Indeed, to perform a valid NEPA analysis, NMFS must not assume, as it does in the current purpose and need statement, that the HCP Alternative fulfills the mandates of the ESA.

As a result, agencies are required to use "all methods and procedures which are necessary," 16 U.S.C. § 1532(2), to "*prevent* the loss of any endangered species, regardless of the cost." *TVA*, 437 U.S. at 188, n. 34. The DEIS does not meet that standard and in fact, if implemented would result in serious harm to listed species in the Middle and Upper Columbia.

Specifically, the DEIS violates the ESA's requirements for three basic reasons. First, the DEIS fails to abide by the ESA's fundamental principle of caution in the face of uncertainty. Second, the DEIS assumes, contrary to law, that the underlying Habitat Conservation Plans (HCPs) are legal in the context of federally regulated hydroelectric dams. Third, the DEIS fails to understand fundamental requirements of the ESA. All three issues are discussed more broadly below.

1. The DEIS Violates the Fundamental Principle of Species Conservation – Erring on the Side of Caution in the Face of Uncertainty.

Effective conservation management requires a conservative, species-protective approach to ensure that management decisions made in the face of uncertainty do not place the species further at risk.[2] An independent peer review panel recently criticized the state of Washington's statewide salmon recovery plan for failing to heed that precautionary principle.[3]

6

The Supreme Court has recognized the importance of this approach in ESA decisionmaking. "Congress has spoken in the plainest of terms, making it abundantly clear that the balance has been struck in favor of affording endangered species the highest of priorities, thereby adopting a policy which it described as 'institutionalized caution.'" *TVA*, 437 U.S. at 194. The ESA's policy of "institutionalized caution" requires that [t]he risk [presented by an action] must be borne by the project, not by the endangered species. . . .Congress clearly intended that [federal agencies] give the 'the highest of priorities' and the 'benefit of the doubt' to preserving endangered species." *Sierra Club v. Marsh*, 816 F.2d 1376, 1386 (9th Cir. 1987). (citations omitted)(emphasis added). NMFS appears headed down an errant path with the DEIS, by placing the risk of uncertainty squarely on the backs of listed stocks.

NMFS' failure to err on the side of protecting listed fish is endemic throughout the DEIS. *See infra* at 12-14. For example, the DEIS states at the very on-set that the purpose of the preferred alternative, the HCPs, is to protect fish while at the same time generating electricity. DEIS at S-2. The ESA strictly forbids this type of analysis. Instead, the ESA requires that the biological needs of the species be identified and addressed. The ESA only allows economics and other interests to come into the determination once recovery and survival thresholds have been met. Setting out the purpose as one that must protect economic interests is inconsistent with the ESA's obligations in this regard.

This problem is also apparent in the DEIS' analysis of scientific gaps. The DEIS specifically states that under Alternative 3, there is no requirement to provide the benefit of the doubt to the species of concern with respect to data gaps or disputes over information. DEIS at S-33. This determination is clearly inconsistent with the ESA and fails to provide sufficient protection to listed species.

Moreover, NMFS specifically finds in the DEIS that the long-term risks to listed stocks is greater than the long-term risks to the PUDs. DEIS at 4-77. Again, the ESA does not allow for this type of imbalance. The "risk of uncertainty on the long-term effects to the species" cannot legally be balanced on the backs

---

[3] Independent Science Panel. Review of "Statewide Strategy to Recover Salmon: Extinction is Not an Option." (2000).

of the fish. Instead, the law requires these risks to be borne by the action. That is, the PUDs' facilities must bare those risks.

Although NMFS and the PUDs might argue that the adaptive management provisions of the HCPs eliminate the illegal risk to the listed stocks, this simply is not the case. The current agreement promises not to use the HCPs' "off-ramp" until year 15 (even if the stocks are plummeting) and the burden of proof requirements under a "no surprises" policy, limit any positive impacts the adaptive management provisions might otherwise present. Simply put, NMFS has negotiated an agreement that while it provides "a substantial amount of planning and financial certainty for the PUDS," it puts a significant risk on the likely survival of the listed species. DEIS at 4-77. We urge NMFS to do what the ESA requires and place the unknown risk on the project, not the species.

2. FERC's Licensing of a Hydroelectric Facility Requires a Section 7 Consultation Process.

The operation of these federally licensed projects should be the subject of a § 7 consultation between the NMFS and the FERC, not the subject of a § 10 incidental take permit (ITP) in an HCP. Issuing an ITP to these projects would be misguided for several reasons.

7

First, § 7 and NMFS' Handbook make clear that the ITPs are available only for nonfederal activities. *See* 16 U.S.C. § 1536(b)(4) & (o) (providing for incidental take statements for federal activities and ITPs for nonfederal actions); HCP Handbook at 1-4 ("[The Section 10] process is designed to address non-federal land or water use or development activities that do not involve Federal action that is subject to section 7 consultation."). As the DEIS makes clear throughout the document, the projects at issue in the HCPs are FERC-licensed projects. *See, e.g.,* DEIS at S-5 (discussing the Wells Hydroelectric Project as a FERC-licensed project). FERC's permitting authority over these projects and its continuing authority over the projects through so-called reopener clauses, constitute federal activities. As such, FERC must consult with NMFS over its actions under § 7 of the ESA. The use of the § 10 HCP process is inappropriate, and likely illegal, in this context.

Second, even if an ITP were appropriate in this context, the ITPs and HCPs would not relieve FERC of its § 7 responsibilities. Section 7 of the ESA requires federal agencies to "insure that any action authorized, funded, or carried out by such agency . . . is not likely to jeopardize the continued existence of any endangered or threatened species." 16 U.S.C. § 1536(a)(2) (emphasis added). Section 7 also requires federal agencies to conserve listed species. 16 U.S.C. § 1536(a)(1). Section 10 of the ESA merely requires that actions not "take" a listed species. 16 U.S.C. § 1539(a). The difference is extraordinary.

We recognize that NMFS acknowledges the need to complete a § 7 consultation on the implementation of the HCPs. However, by blessing the HCPs first, NMFS simultaneously renders the § 7 consultation process meaningless and places the agencies in a position that, very likely, will result in a process that is contrary to the law. The "no surprises" policy of the HCPs would negate the ability of the agencies to insert provisions into the FERC licenses that the agencies found necessary to comply with their § 7 conservation, survival, and recovery obligations. Contrary to the "no surprises" assurances that certain commitments will not be revisited, NMFS would illegally restrict the ability of FERC and NMFS to comply with their § 7 responsibilities. In the very least, the consultation process must occur prior to any further development or agreement to the HCPs.

Third, a "no surprises" cap on these projects' responsibilities is particularly troubling due to the river-based nature of these operations and each individual dam's impacts on migrating salmon and steelhead. To justify the promises of certainty in the face of rapidly changing conditions, NMFS and Fish and Wildlife Service asserted in their "no surprises" rulemaking that the agencies can rely on conservation contributions from neighboring land owners or voluntary conservation organizations to compensate for

the cap on the permittee's responsibilities. *See* 63 Fed. Reg. 8859 (1998), codified at 50 C.F.R. §§ 17.22(b)(5), (6) & 17.32(b)(5), (6) (1998). This justification makes absolutely no sense for the salmon and steelhead of the middle and upper Columbia River, which will not survive dams that prove to be harmful regardless of the extent to which neighboring landowners step up their conservation contributions. In essence, there is no "neighbor" to make up for the adverse impacts to the species.

Finally, no surprises assurances have already created significant new risks for endangered species as they have been applied over the past five years to nonfederal activities. "No surprises" guarantees tend to lock-in an HCP's initial design, rendering adaptive management meaningless, by setting extremely high burdens of proof for the Services, requiring additional mitigation to first occur on public lands, requiring any additional mitigation to be fully subsidized by the public, and/or allowing any additional mitigation to be voluntary. Even in cases where an HCP's initial provisions are more adequate, changes and additions to these measures may well become necessary over time, including as a result of changes in the permittees' resource management practices, changing environmental conditions, or other foreseeable and unforeseeable circumstances. Rather than repeating our general concerns regarding the no surprises policy here, we include by reference, the National Wildlife Federation's comments on the "no surprises" policy rulemaking and American Lands' comments on the Scoping Notice for these HCPs. These concerns are heightened by the fact that NMFS has found the listed species at issue in these HCPs to be some of the most imperiled in the Columbia River Basin. This is not a time to add to the obstacles these species must face, but rather a time to provide the maximum protections afforded by law and policy.

3. The DEIS Misunderstands the Requirements of the ESA.

The DEIS fundamentally misunderstands the requirements of the ESA and its relationship to hydroelectric projects. In several places, the DEIS states that NMFS cannot legally mandate drawdown or dam removal until project relicensing. *See, e.g.*, Table 2-8 at 2-57 or 4-29 & 2-45, respectively. This is
8 simply not the case. These projects currently hold licenses that contain reopener clauses that allow FERC to change or revoke the licenses due to fish and wildlife concerns. As a result, FERC retains ongoing authority and jurisdiction over these projects. Courts have found that this ongoing jurisdiction requires the federal agency with this authority to reinitiate consultation and to take whatever action necessary to protect the listed species. *See WaterWatch of Oregon v. U.S. Army Corps of Engineers*, Civ. No. 99-861-BR (D. Or. June 7, 2000) (finding that a reopener clause in a federal permit required the Corps to reinitiate consultation over a water withdrawal). NMFS' elimination of the dam removal alternative is simply inconsistent with federal law. We strongly urge the agency to reconsider its elimination of this alternative.

Additionally, the ESA requires NMFS to consider alternatives that are much more protective of fish than the HCPs proposed in Alternative 3 of the DEIS. The ESA requires that an HCP minimize and mitigate the taking of endangered and threatened species to the "maximum extent practicable." 16 U.S.C. § 1539(a)(2)(B)(ii). As discussed earlier, the DEIS fails to consider any alternative that would be more protective of fish, such as the installation of sluiceways at each project. NMFS' failure to consider this and other, more protective alternatives violates the ESA's "maximum extent practicable" requirement. As Courts have held, "the most reasonable reading of the 'maximum extent practicable' nonetheless requires the Service to consider an alternative involving greater mitigation . . . .'The Administrative Record must contain some analysis of why the level or amount [of take] selected is appropriate for the particular project at issue.'" *National Wildlife Fed'n. v. Babbitt*, 128 F.Supp.2d 1271, 1292 (E.D. Cal. 2000) (*citing Sierra Club v. Babbitt*, 15 F.Supp.2d 1274, 1279-82 (S.D. Ala. 1998). NMFS must not only show that the mitigation proposed in the HCPs is practicable, but must demonstrate that a higher level of mitigation would be impracticable. Just as NMFS cannot satisfy NEPA's range of alternatives requirement with the discussion of only 2 alternatives, such a narrow range of alternatives similarly fails to satisfy the requirements of the ESA.

Also disturbing is the manner in which the DEIS treats permit revocations. The ESA requires revocation of the permit if the permitee is not meeting the permit's terms and conditions. 16 U.S.C. § 1539 (a)(2)(C). However, the HCPs appear to limit this revocation authority in two significant ways. First, the HCPs only allow revocation after year 15. So, the PUDs could fail to meet the terms and conditions of the HCPs for 14 years without recourse. DEIS at S-16; 2-33. Second, the revocation at year 15 may be exercised only if NMFS is specifically seeking drawdown, dam removal, and/or a non-power operating action. Neither limitation is consistent with ESA requirements. We urge NMFS to review the law and the underlying HCP agreements to ensure consistency.

Finally, NMFS' failure to provide an adequate review of the HCPs' monitoring and evaluation programs undermines the very essence of the ESA. The monitoring and evaluation of the HCPs are critical for compliance with the ESA. Without accurate and adequate monitoring and evaluation mechanisms, NMFS and FSW will be unable to determine, in any scientifically or legally credible manner, whether the PUDs are complying with the HCPs and thus, with the ESA. The DEIS fails to adequately address the obvious limitations with the alternative's monitoring and evaluations processes. We urge the agency to do a more thorough analysis of the limitations of these processes and to articulate how the agency will be able to ensure compliance with federal law.

Federal Power Act

9 The DEIS specifically states that the HCPs would "supercede the existing FERC license articles and settlement agreements as they pertain to anadromous fish." DEIS at 1-9. It is also the intention of the PUDs that the HCPs satisfy NMFS' obligations pursuant to sections 18, 10(a), and 10(j) of the Federal Power Act. However, the DEIS falls far short of including the analysis and requirements necessary to supercede these statutory requirements.

Both the Federal Power Act (FPA) and NEPA obligate a hydroelectric licensee to incorporate pre-project conditions in the relicensing process. As currently written, the DEIS and HCPs limit these requirements. Section 10 of the FPA establishes two mechanisms for requiring the analysis of pre-project conditions. First, section 10(a) requires an assessment that ensures the "equal consideration" of non-power values, including fish, wildlife, recreation, and environmental quality, when relicensing a hydroelectric facility. 16 U.S.C. § 803(a). The FPA's legislative history further clarifies that the intent of the FPA's 50-year cap on hydroelectric licenses was to ensure that the commitment of a river to power production be reevaluated anew at the time of relicensing. *See, e.g.,* Statement of Theodore Roosevelt, H.R. Rep. No. 507, 99th Cong., 2nd Sess. 11 (1986) stating that "[t]he public must retain the control of the great waterways. It is essential that any permit to obstruct them for reasons and conditions that seem good at the moment should be subject to revision when changed conditions demand.") A proper assessment of giving equal consideration cannot be determined without first understanding how the project has impacted environmental resources and how these resources could be restored. The DEIS utterly fails to address those issues by ignoring the pre-project conditions. Including a dam removal alternative would help rectify this serious oversight.

Second, § 10(j) of the FPA also compels a pre-project analysis by requiring that relicensing be conditioned upon the inclusion of 'adequate and equitable" fish and wildlife protection, mitigation, and enhancement (PM&E) measures. 16 U.S.C. § 803 (j). This first step in determining the appropriate level of PM&E measures is to identify the historic conditions within which fish and wildlife existed prior to the hydroelectric project. The goal is to understand the key ecological conditions required for a healthy, self-sustaining fish and wildlife populations, and to strive to restore the physical, chemical, and physiological processes that create and maintain those conditions. However, reaching this goal is impossible without

first assessing the conditions of the ecosystem prior to dam construction. Again the DEIS is woefully lacking in this analysis.

Third, the DEIS provides no analysis of whether the HCPs at issue satisfy the FPA. It seems obvious that NMFS has blinded itself to these requirements. Certainly, by not analyzing the impacts to the FPA requirements, NMFS has failed to present the issues squarely for the public and decision-makers. The FPA grants certain authorities to NMFS to protect fishery resources, (listed and non-listed), affected by the hydroelectric project. The DEIS fails to analyze whether the HCPs' measures will satisfy such obligations. We urge the agency to complete a thorough analysis of how the proposed alternative will comply with the FPA requirements.

Finally, the very concept of the HCPs at issue in the DEIS circumvent the FPA requirements by including a "no surprises" assurances. As discussed earlier, the "no surprises" policy pre-supposes both the content and the term of years for the PUD FERC licenses. This is particularly disconcerting in terms of content where FERC has regularly inserted reopener clauses into its licenses in order to ensure "equitable treatment for fish and wildlife over the terms of the license agreement. The "no surprises" policy in the HCPs would eliminate FERC's ability to ensure compliance with this section of the FPA and many of its own license terms.

Clean Water Act

10 The CWA requires that all federal agencies "having jurisdiction over any property or facility . . . shall be subject to and comply with" all applicable federal, state, and local water quality laws. 33 U.S.C. § 1323. As a federal court has recently held, dams are no exception to this rule. See National Wildlife Fed'n v. U.S. Army Corps of Engineers, 92 F. Supp.2d 1072 (D. Or. 2000) (holding that the Corps' dams on the lower Snake River must comply with state water quality standards). As the permitting agency, FERC has jurisdiction over the operation of these dams. Nowhere in the DEIS, however, is there an analysis of whether any of the alternatives will comply with water quality standards. NMFS must analyze the water quality impacts of these projects and ensure that state water quality standards are met.

In addition, as a result of the actions analyzed in this DEIS, NMFS will issue an incidental take permit or an incidental take statement. However, both the ITP and the ITS require state certification under section 401 of the CWA. 33 U.S.C. § 1341. To the best of our knowledge, NMFS has not acknowledged receipt of such certification from the applicants. We ask the agency either to identify where in the DEIS this certification is discussed or to seek such certification prior to issuance. To issue one of these permits without a certification is a violation of section 401 of the CWA.

Inadequacy of HCP Provisions

11 The HCPs establish a no net impact standard for salmon and steelhead at the Rocky Reach, Rock Island, and Wells hydroelectric projects. The key components include a 91 percent total project survival rate, including an independent 95 percent juvenile passage rate, and 9 percent compensation through hatchery and tributary improvement programs. The DEIS clearly illustrates the shortcomings of the proposed standards and the unacceptable risk placed on the species as a result. Nonetheless, NMFS' analysis overlooks the serious shortcomings with the HCPs.

1. Adult and Juvenile Survival Standards Are Insufficient.

The DEIS must determine whether the adult and juvenile survival standards proposed in the HCPs are sufficient to recover the species and importantly, whether it is even possible to measure compliance with the proposed standards. The DEIS fails on both accounts.

Perhaps one of the most significant problems with Alternative 3 is the inability to accurately measure the key components of the HCPs – juvenile and adult survival standards. The DEIS makes clear that there is considerable uncertainty surrounding the available survival information for juvenile and adult salmonids passing the Mid-Columbia hydroelectric projects. Further, the DEIS states that (1) methodologies do not currently exist to measure total project survival for all species for juvenile migration, and (2) there are no specific plans to assess overall adult survival at the projects due to the lack of accurate methods to do so. Despite a lack of scientifically credible methods to determine whether the PUDs are meeting the proposed survival standards, NMFS relies on the standards when evaluating risks to the species of the proposed action. The DEIS fails to explain such reliance or evaluate the risk associated with standards that cannot be measured. NMFS cannot issue an incidental take permit while at the same time expressly acknowledging an inability to determine whether the applicant is in compliance with its terms.

Until such time as accurate assessment methods are developed, NMFS proposes to utilize representational studies of yearling spring chinook and steelhead to determine juvenile survival of all species and proposes nothing with regard to measuring total project survival, which includes adult survival. In the absence of adequate methods to measure whether the specified standards are being met for all of the life stages of all covered species, the standards are meaningless. Yet, the DEIS does not account for this considerable uncertainty in its analysis.

Compounding the risk to species is the provision that in the absence of methods to accurately determine unavoidable project mortality – defined as 5 percent juvenile dam passage mortality and 4 percent mortality from all other project effects, including adult mortality – NMFS assumes that the underlying estimates are correct. There is absolutely no data to justify such an assumption, and making this assumption runs counter to the fundamental principles of the ESA requiring that uncertainty be resolved in favor of the species. *See supra,* at 7-8. Therefore, until the PUDs accurately assess the specified survival standards, NMFS should assume non-attainment of the standards.

Moreover, the assumptions regarding the underlying mortality estimates serve as a disincentive for the PUDs to develop and implement studies of total project survival in a timely manner. The HCPs allow the
12 PUDs to transition from Phase I to Phase III based solely on attainment of the 95 percent juvenile survival standard. As a result, the PUDs can forego studying total project survival, relying instead on the unjustified assumptions in the HCPs. Again, this result runs afoul of the ESA's cautionary principles.

We acknowledge the difficulty in evaluating certain standards and that the HCPs call for such protocols to be developed at some future date. However, NMFS may not rely on survival standards for which there are no technologies available to evaluate when determining whether the proposed HCPs comply with the ESA. A promise of future assessments, coupled with assumptions that standards are being met in the absence of such assessments, falls far short of what the ESA requires, and cannot be used to support any conclusions as to the HCPs' adequacy. *See, e.g., Sierra Club v. Marsh,* 816 F.2d 1376 (9th Cir. 1987) (the
13 benefit of the doubt must be given to species not the action). There must be scientifically credible means to determine whether the standards set forth in the draft HCPs are being met *prior* to issuance of an incidental take permit. And, NMFS must consider the accuracy, reliability, and feasibility of the proposed measuring techniques in its analysis of the HCPs.

Recent actions undertaken by Chelan County PUD highlight the risk posed to the species by failing to develop agreed-upon methods for assessing whether survival standards are being met for all species prior to implementation of any HCPs. Despite lack of support from tribal, federal, and state fishery experts,

Chelan County PUD concluded that the Rocky Reach Hydroelectric Project was providing 95 percent juvenile dam passage survival and decided to forego the minimum spill requirement set forth in the HCPs. The PUD relied on inadequate analysis to support its conclusion, and ignored the requirement that all parties agree that the standard has been met prior to foregoing spill. Similar situations are likely to occur in the absence of measurable criteria.

Even if the 95 percent juvenile dam passage survival standard was measurable for all species, NMFS' analysis of the expected survival improvements and their adequacy in recovering the species is deficient in several respects. First, the HCPs call for the PUDs to maintain a 95 percent juvenile dam passage survival standard over only 95 percent of the run. NMFS fails to analyze the effect of protecting only 95 percent of the run and whether this approach is even legal under the ESA. Additionally, the HCPs allow for the exclusion of spring migrating chinook smaller than 50 mm in length from the 95 percent juvenile dam passage survival for the full run of that species in the event turbine intake screens are installed certain instances. The DEIS does not consider the effect of such exclusion on the species.

14

Finally, the PUDs, rather than NMFS, have the ultimate decision on what measures to implement during Phase I of the HCPs. The minimum required of the PUDs is that they demonstrate "steady progress" toward project survival standards throughout the duration of Phase I. However, the DEIS provides no criteria to determine adherence to steady progress, and importantly, states that such adherence will not be monitored until actual implementation of the HCPs. The result is that despite Phase I beginning in 1998, NMFS is not requiring the PUDs to comply with the steady progress requirement. Failure to provide steady progress delays implementation of critical protection measure and shifts the burden onto the species.

The insufficient analysis of the 95 percent standard, the lack of scientifically credible methods by which to determine whether the PUDs are achieving the HCP standards, and the lack of a requirement to provide the benefit of the doubt to the species of concern with respect to information gaps or disputes results in insufficient protection for the species.

We recommend that NMFS identify and evaluate feasible measurement protocols to assess compliance with all aspects of the survival standards. Such protocols should address all species and all life stages, including adult survival. In conjunction with development of study methodologies, NMFS should evaluate the potential impacts on the species that may result from implementation of such studies. Further, any uncertainties with regard to whether standards are being met must be resolved in favor of the species.

2. The DEIS Lacks Any Adequate Analysis of the Off Site Mitigation Proposals.

The DEIS notes that the ultimate goal of the HCPs is to achieve no net impact to each species covered by the HCPs. This standard requires a 9 percent compensation for unavoidable project mortality through two programs – 7 percent compensation to be provided through hatchery programs and 2 percent compensation provided through tributary habitat improvement programs. However, the DEIS fails to provide a detailed evaluation of either program, including the manner in which NMFS will assess the projected benefits. Rather, the DEIS acknowledges that there are no means to assess these benefits and then simply assumes that the funding and supplementation levels contained in the HCPs are adequate.

15

a. Tributary Improvements

A critical component of any salmon protection and recovery effort will involve the protection and restoration of salmon and steelhead habitat throughout the basin. Thus, while a tributary habitat improvement fund is a laudable goal, it must be accompanied by measurable actions and objectives. The

16

proposed tributary fund in the HCPs fails to meet that requirement and as a result, raises questions about the legality of such a program under the ESA.

The DEIS provides no analysis to support the proposed tributary habitat improvement fund levels established in the HCPs or to suggest that the fund will result in the 2 percent compensation for unavoidable project mortality as intended. The fund is defined in monetary terms, with no connection to specific habitat improvement measures or goals necessary to meet the habitat needs of salmon and steelhead. And, although the DEIS states generally that habitat conditions are expected to improve, there is no way to measure the actual benefits of such improvements or determine whether the PUDs are complying with the 2 percent compensation standard. Despite this inability to measure and the uncertainty surrounding the fund, the DEIS quantifies and relies upon expected survival increases for steelhead and spring chinook resulting from such improvements. The DEIS fails to support its finding that the fund will either provide 2 percent compensation or provide the projected survival benefits.

Additionally, the DEIS does not explain how the funding structure may affect when or whether improvements are made and survival benefits realized. Similarly, the DEIS fails to explain how the funding structure will actually achieve interim goals for recovery. The QAR analysis assumes that survival improvements from off site mitigation will be realized immediately, even though the funding for such improvements is spread out over the 50 years of the permit. NMFS clearly understands that the survival improvements cannot be immediately realized. And yet, the DEIS, while acknowledging this discrepancies, simply ignores the problem. NMFS' avoidance technique and lack of analysis presents an illegal burden of risk on the listed species and violates both the ESA and NEPA.

17 Finally, the DEIS fails to explain why Douglas County PUD's contribution to the tributary improvement fund would be reduced by half in the event that the PUD is achieving 95 percent juvenile dam passage survival or higher at the Wells dam. There is no justification for linking the tributary habitat fund solely to the juvenile dam passage survival standard. Such a reduction runs counter to the goal of attaining no net impact at the project and is not considered in the DEIS estimation of survival benefits. The projected benefits, although not supported by data or scientific analysis, are based on tributary improvements to mitigate for 2 percent of unavoidable project mortality. Changing the contribution level without scientific justification is irrational and contrary to law.

b. Hatchery Mitigation

18 The DEIS fails to adequately analyze the hatchery supplementation component of the HCPs. Not only does the QAR analysis fail to consider a long-term program, but NMFS also provides no analysis to support a program that compensates for 7 percent unavoidable project mortality. Although the HCPs rely on 7 percent compensation through hatchery programs to attain the underlying goal of no net impact, NMFS expressly states that it cannot guarantee a program at that level. The DEIS notes that any hatchery program must be designed and implemented in a manner consistent with recovery goals, but provides no information as to how that might be accomplished nor whether such consistency will prevent the PUDs from meeting the required 7 percent hatchery compensation. Nevertheless, the analysis fails to factor in the potential for non-attainment of 7 percent compensation through the hatchery program, and in turn, the no net impact standard. The failure of this analysis raises questions as to whether the HCPs and the no net impact standard meet the obligations of the ESA.

Although the DEIS identifies continued supplementation as an important factor to consider and clearly a key component of the HCPs, the QAR fails to analyze the impacts of a long-term supplementation program intended to provide the 7 percent compensation. In fact, the QAR analysis assumed a short-term supplementation program would be suspended upon attainment of certain goals, while supplementation under the HCPs would continue unless shown to have a negative impact to ESA listed species. 19

Insufficient information about the hatchery program, in combination with uncertainty surrounding both the survival standards and the tributary program, preclude NMFS from fully assessing the environmental impacts of the HCPs and drawing any conclusions as to its sufficiency under the ESA.

3. Inconsistencies between QAR & DEIS Call DEIS Analysis into Question

The DEIS relies on the Quantitative Analytical Report (QAR) to assess the impacts of implementing the survival standards and tributary habitat improvement measures in the HCPs. NMFS' reliance on the QAR analysis is misguided for several reasons. First, the QAR "assumed that the survival improvements called for at the hydroprojects, and through off-site mitigation, occur instantaneously," when in fact, as the DEIS notes, the survival benefits from the measures in the HCPs may not be realized for years. DEIS at 4-11. The QAR also assumes that Grant County PUD's Priest Rapids Project has achieved a 95 percent juvenile survival standard, similar to the juvenile dam passage survival standard called for in the HCPs. However, the DEIS provides no support for this assumption. As discussed above, the QAR also fails to adequately assess the proposed hatchery supplementation program. Finally, the QAR incorporates the survival improvements called for in the Federal Columbia River Power System Biological Opinion, even though such standards are not currently being met. The QAR relies upon unsupportable assumptions contrary to the requirement that NMFS articulate a rational connection between its findings and the available facts. Inconsistencies between the QAR and available facts call into question NMFS' reliance on the analysis to draw any conclusions about the adequacy of the HCPs. 20

Conclusion

The DEIS fails to demonstrate that the proposed HCPs provide sufficient protection of anadromous salmon and steelhead. It relies on immeasurable standards and too often places the risk of uncertainty associated with such standards on the species. A plan that is to govern salmon and steelhead protection measures at the Rocky Reach, Rock Island, and Wells hydroelectric projects must contain significantly more certainty with regard to attainment of standards, effectiveness of standards in light of all the impacts in the Columbia River Basin, and must be conservative in favor of ESA-listed species. The DEIS does not provide sufficient analysis of the environmental impacts of the alternatives to warrant adoption of the HCPs.

Thank you for the opportunity to comment. Please feel free to call if you have any questions regarding these comments.

Feb. 15, 2001

Dear Sirs:

We are residents of East Wenatchee, and have been involved in conservation issues for many years. We have worked through the Chelan/Douglas Land Trust, the Foster Creek Conservation District, and The Nature Conservancy of Washington to preserve riparian habitat and aid salmonid survival and restoration in the Mid-Columbia Region.

We heartily endorse the HCP as prepared by the Chelan County PUD. While we cannot comment with any authority on the specific recommendations and actions, we support the increased certainty re: future licensing and take issues that the HCP addresses. We don't feel that dam breaching or removal is a reasonable alternative, and therefore extensive mitigation measures need to be pursued as outlined in the HCP.

We look forward to working with the PUD in the near future regarding conservation easements on riparian lands on both the tributaries and the main stem of the Columbia. We have already met with the senior staff of the PUD and look forward to more meetings to plan ways that local conservation groups can work with the PUD to ensure healthy fish stocks into the future. We agree with the comment: "extinction is not an option," and we welcome the proactive approach as outlined in the HCP.

Thank you for the opportunity to submit these comments, and we look forward to seeing the implementation of the HCP.

Sincerely Yours,

Eliot W. Scull

Christine E. Scull

February 12, 2001

To Whom It May Concern:

As a resident of North Central Washington, a fruit grower and the President of Stemilt Growers, Inc., I want to comment on the Habitat Conservation Plan for salmon recovery in our area.

Like almost everyone I know I have a high interest in the salmon recovery success. I work with over four hundred fruit growers in Central Washington. We employ well over a thousand people in our packing plant and orchards. We rely on the natural resources of the mid Columbia region to support these family farms and to employ these hundreds and hundreds of people in production jobs. I would like to endorse enthusiastically the principles behind the Habitat Conservation Plan (HCP) now being reviewed by your agency for the fish resources of the Columbia River.

Ample water is necessary to irrigate our orchards. Reliable low-cost electricity is necessary to pump that water to the trees, to run the packing lines which process the fruit and enable the controlled atmosphere storage rooms to maintain their precise conditions for top marketing of the products. In an era when so many other pressures are squeezing the agricultural industry, cooperative approaches like this HCP help by providing more long-term certainty regarding water supplies and electric power. It would be a shame to remove yet one more cornerstone of our increasingly shaky foundation.

As we understand it, the HCP approach lets the knowledgeable people at the Chelan County PUD use their insight and understanding to achieve measurable results on fish issues. As a business owner, I can appreciate the approach. Regulatory burdens too often lead to nothing but long drawn out legal battles.

The region will best be served by allowing Chelan County PUD to match it's fish protection measure with other aspects of hydroelectric operation, especially with the guaranteed review of the results provided for in the HCP. Stemilt Growers adds its voice to those calling for implementation of the agreement as it has been presented.

Thank you,

Thomas K. Mathison
President – CEO

OWNF

Mr. Bob Dach
NMFS, NWR, Hydro Program
525 NE Oregon Street, Suite 420
Portland, OR 97232-2737

Dear Mr. Dach:

The Okanogan & Wenatchee National Forest (OWNF) would like to submit the following comments on the *Anadromous Fish Agreements and Habitat Conservation Plans, Draft Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* which we received January 2, 2001. We have organized our comments in two categories; (1) general and (2) specific, according to page numbers from the DEIS. We hope this facilitates your review and response.

General Comments

1

The DEIS has been reviewed by OWNF Fishery Biologists, Hydrologists, District Rangers and other specialists from the following Ranger Districts: Leavenworth/Lake Wenatchee, Entiat/Chelan, Methow Valley, and Tonasket. The consensus of the reviewers is that the DEIS chapters covering Affected Environment and Environmental Consequences with respect to the associated tributaries tend to be overly general, out dated, and in some cases innaccurate. The developmental lifespan of the HCP/DEIS has been such that it does not reflect recent advances in a number of areas:

- Watershed Restoration: The DEIS hints at the possible effects of these ongoing activities but is short on specifics.
- Watershed Analyses: The DEIS utilizes USFS documents in an uneven manner, often overly generalized. More recent documents are unutilized.
- Watershed Monitoring: Aquatic habitat monitoring in the tributaries has intensified in recent years yielding new information (particularly regarding thermal and sediment regimes) that would increase the quality of the DEIS.
- Biological Assessments: The associated tributaries are now covered by analytical baselines completed according to the NMFS ESA-matrix for steelhead and spring chinook salmon and the USFWS ESA-matrix for bull trout. These BAs are typically updated annually and include a wealth of information and interpretation that is not reflected in the DEIS.

It is our opinion that sections of the DEIS that pertain to the associated tributaries are inadequate to serve as a basis for effective protection and restoration of Plan species habitat in the tributaries. Requiring the DEIS to be updated would serve little purpose other than to further delay implementation of the HCP. The OWNF is concerned that implementation of the HCP will not be timely enough to reverse the declining population

trends of Plan species. It is acknowledged that attempts to keep the DEIS up-to-date regarding the tributaries would continually lag behind. The process of watershed analysis is iterative by design to account for changes in the dynamic processes that shape watersheds and the advances in our knowledge of these processes. To solve this dilemma, we propose that the parties to the HCP add wording to the adaptive management sections of the DEIS that would require the following:

- Prior to selecting projects for the associated tributaries, the Tributary Committee conduct a thorough review of the current status of Plan species and habitat limiting factors within the associated tributaries.

- The PUDs become involved (technically and financially) in future watershed analyses of the associated tributaries.

The OWNF supports Alternative 3, particularly the Tributary Conservation Plan and the dam passage survival standards. The OWNF has some reservations regarding the Hatchery Compensation Plan. The policy and direction of the OWNF is to manage habitat for natural production; therefore, it is mandatory that Forest Fishery Biologists carefully review any HCP-driven proposals to artificially supplement salmonid populations within the National Forest. It is understood that artificial supplementation may be required to restore some anadromous species. The Forest's opinion is that artificial supplementation should be applied as a short-term stop-gap measure and phased out over time. Because of concerns about broodstock mining, appropriate release sites, and species interactions (competition, disease, genetic integrity) the OWNF expects to be directly involved in reviewing plans for hatchery supplementation.

The Forest is one of the principal aquatic habitat managers in the Wenatchee, Entiat, Methow, and Okanogan Subbasins. The Forest expects to be an integral part of the Tributary Committees proposed by the HCP.

Monitoring and adaptive responses will be keys to evaluating the success of the HCP. The Forest expects to be involved in reviewing monitoring results after the HCP is implemented. The Forest expects to make future recommendations based on HCP monitoring results.

Specific Comments

2 *Page S-40*: Vegetation impacts during drawdown should also disclose the increase of noxious weeds if drawdown occurs.

3 *Page 1-31*: "Any additional measures NMFS deems necessary for the permit would be detailed in the biological opinion." and *page 2-2* "If NMFS determines that the proposed measures are not adequate to ensure the continued existence of the species, a reasonable and prudent alternative to the proposed action would be developed". These statements give the appearance that NMFS has not disclosed all of the actions associated with the alternatives and consequently has not disclosed all of the effects. We cannot comment on the proposed action and effects unless they are disclosed in their entirety.

4 *Page 2-40*: Project Cumulative Effects appears incomplete. 40CFR1508.7 defines cumulative effects as: "the impact on the environment which results from the incremental impact of the action when added to other past, present and reasonably foreseeable actions regardless of what agency (Federal or non-Federal) or person undertakes such action." This DEIS addresses neither impacts of past actions nor

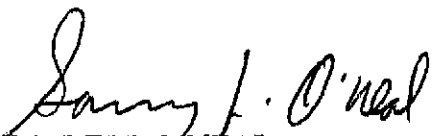
reasonably foreseeable actions. It is our opinion that reasonably foreseeable actions would include all actions proposed in each of the tributaries including cumulative effects of DEIS hatchery supplementation programs combined with current hatchery programs including coho re-introduction during implementation of alternatives 2 or 3 and actions proposed as restoration projects in the watershed analyses for each of the tributaries. What are the expected effects of all the smolt outplanting on wild fish, both in the tributaries and during migration out to the Columbia estuary?

Page 3-68: The reported Entiat River spring chinook salmon average escapement estimates (redds) based on dam counts (turnoff estimates) are clearly in error. The OWNF considers spawning ground surveys to produce more accurate estimates of escapement and population trends and suggest the use of redd count expansions as recommended by Carie (1996). For example: if Entiat steelhead escapement is 5 estimated by subtracting Wells Dam counts from Rocky Reach Dam counts and then subtracting Wells hatchery broodstock take, the resulting escapement estimates are often negative numbers (1982, 1983, 1984, 1991 & 1992). Chapman et al. (1994) concluded that steelhead escapement to the Entiat River cannot be accurately calculated.

Page 3-89: The reported average monthly flows in the lower Entiat River are incorrect and inconsistent 6 with the flows correctly depicted in Figure 3-9.

Section 4.1.3.2 identifies specific projects that would be implemented under alternative 3. The projects generally relate to reducing erosion, sedimentation and turbidity. These are worthy goals; however, none of these tributaries are on Washington Sate Department of Ecology's 303(d) list for sediment or turbidity. They are 303(d)-listed for instream flows. An action that would increase instream flows while 7 reducing the risk of landslides after catastrophic wildfires is captured in the OWNF dry site strategy. This strategy of reducing vegetative stocking and fuel levels in fire-prone landscapes would increase streamflows in the tributaries, especially during the critical base-flow time of year. This strategy has been subjected to a blind peer review. The OWNF has more than 500,000 acres of dry site in these four tributaries that could benefit from some form of stocking control and fuels reduction over the next 50 years.

Sincerely,



SONNY J. O'NEAL
Forest Supervisor

March 8, 2001

National Marine Fisheries Service
525 NE Oregon Street, Suite 420
Portland, Oregon 97232-2737

Dear Sir/Ma'am:

The United States Department of Agriculture-Wildlife Services (WS) would like to thank you for the opportunity to review and comment on the DEIS regarding the proposed Anadromous Fish Agreements and HCP's for the Wells, Rocky Reach, and Rock Island hydroelectric projects.

After reviewing the document we have compiled a list of comments based on the context of the DEIS and how it relates to the Cooperative Service Agreements (CSA) we have with the Chelan and Douglas County PUD's.

The objectives and goals of the CSA at Rocky Reach and Rock Island dam are to reduce predation on downstream migrant salmonid smolt and steelhead fingerlings by populations of predatory gulls, cormorants, and other piscivorous birds. This includes the reduction of damage to electrical utilities/structures caused by nesting/roosting cormorants.

In Douglas County, the CSA with Wells Hatchery directs WS to reduce or alleviate predation on juvenile salmonids by piscivorous birds, primarily mergansers, cormorants, gulls, herons, and diving ducks. The CSA at Wells Dam is in place to maintain the integrity and function of the existing overhead wire exclusion system over the tailrace area, thus reducing predation on juvenile salmonids by piscivorous birds. This wire exclusion system is also in place over the rearing ponds at Wells Hatchery.

Our comments focus on the lack of information and discussion of piscivorous birds at each of the hydroelectric projects. Predation on salmonid species by fish-eating birds is well documented in the literature, and we find the omission of all piscivorous bird species but gulls to be a serious oversight of the DEIS.

COMMENTS

Section 2.2.4.3 Predation

WS

1 The last paragraph (p. 2-22) discusses bird predation and measures taken to reduce the damage. The methods listed include: *wires, propane cannons, and other pyrotechnic methods*. It is important to reveal that lethal methods are used to reinforce the nonlethal methods. Shooting in the direction of, but not at, target birds is sometimes augmented by intentional shooting of individual target birds. The intent of such shooting is to enhance the scaring efficiency of firearms and pyrotechnics by training the birds to anticipate injury when they hear explosions. Birds that learn to fly beneath the wires strung over the tailraces, at certain projects, are shot. The discussion of lethal measures should not be a red-flag issue.

Section 2.3.1.1. Wells Hydroelectric Project

2 ▫Measures Planned

2. Juvenile Passage

C. Predation

Part C under Juvenile Passage reads: *continue to refine and implement a northern pikeminnow removal program.* It is our understanding that Wells Hatchery is affiliated with Wells Dam. If Wells Hatchery is indeed a facility within the Wells Hydroelectric Project then mention must be made to the piscivorous bird program at the hatchery. As mentioned earlier, our CSA with Wells Hatchery includes a multitude of fish-eating birds. Similar wording used in section 2.3.1.2., paragraph 4, bullet 4 on avian predation would be suggested.

Section 2.3.1.3. Rock Island Hydroelectric Project

3 Unlike the two hydroelectric projects described prior to Rock Island, there is no mention in this section as to the piscivorous fish and bird programs in place, nor mention of their continuation in the future. We believe there should be mention made to these programs.

Section 2.3.3.8. HCP Conservation Plan and Compensation Measures

▫Wells Dam

4 Once again there is no mention of Wells Hatchery. Does the hatchery compliment the dam and are both operated by the Douglas PUD? Wells Hatchery is not combined under the proposed plan for Wells Dam, nor is it mentioned anywhere under section 2.3.3.8. We believe that Wells Hatchery needs to be included, either separately or under Wells Dam.

Section 3.2.9.2. Project Area Rearing

▫Predation

5 The lack of data, literature, and discussion of piscivorous birds is problematic. The DEIS has but one reference (Ruggerone, 1986) to the only piscivorous bird species mentioned. Gulls are only one of many fish-eating birds found at Wells, Rocky Reach, and Rock Island dams. WS is under agreement to control cormorants, herons, mergansers, diving ducks, and terns. A separate section discussing piscivorous birds and their associated damage is needed. Failure to address this issue could result in a forced cessation of bird control activities for Chelan and Douglas County PUD's due to insufficient NEPA. We would conclude that a deeper look at predator/pest management programs be taken.

Please let us know if we can be of assistance in providing information needed for this or other analyses.

I would like to thank you again for allowing Wildlife Services to review and comment on the DEIS regarding the proposed Anadromous Fish Agreements and HCP's for the Wells, Rocky Reach, and Rock Island hydroelectric projects. We hope our comments will be of some help in the completion of a thorough and complete Environmental Impact Statement.

Sincerely,

J. Gary Oldenburg
State Director, WA/AK

Dear Mr Dach

The Department is currently reviewing the Draft Environmental Impact Statement (DEIS) for the Anadromous Fish Agreement and Habitat Conservation Plans for the Wells, Rocky Reach and Rock Island Hydroelectric Projects, Washington. We note in the letter accompanying DEIS that comments are due March 29, 2001.

I am currently working with the Fish and Wildlife Service and the Bureau of Indian Affairs to develop the Department's comments. Because of the magnitude of these issues the Department will need additional time to discuss and coordinate our concerns prior to submitting comments on the DEIS.

We therefore respectfully request a time extension until May 1, 2001 to provide comments. I appreciate your cooperation in this matter. If you have any questions or require any additional information you can contact me at (503) 231-6157 and preston_sleeger@ios.doi.gov.

Sincerely,

Preston A. Sleeger
Regional Environmental Officer

ER 01/0082

Mr. Bob Dach
National Marine Fisheries Service
525 NE Oregon Street, Suite 420
Portland, Oregon 97232-2737

Dear Mr. Dach:

The U.S. Department of the Interior (Department), through its bureaus the Fish and Wildlife Service (Service) and the Bureau of Indian Affairs (BIA), has reviewed the Draft Environmental Impact Statement (DEIS) for the Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects, Washington. In the DEIS, the National Marine Fisheries Service (NMFS) considers whether to authorize incidental take permits pursuant to the Endangered Species Act Section 10(a)(1)(B) for 50-year anadromous fish agreements and habitat conservation plans (HCPs) with two Washington State public utility districts (PUDs) operating three Federal Energy Regulatory Commission (FERC) licensed hydroelectric projects on the mid-Columbia River. The Department offers the following comments for your consideration in the development of a final environmental impact statement (FEIS). These comments were prepared under the authority of and in accordance with provisions of the National Environmental Policy Act (42 U.S.C. 4321 et seq.; 83 Stat. 852), as amended, the Fish and Wildlife Coordination Act (16 U.S.C. 661 et seq.; 48 Stat. 401), as amended, the Endangered Species Act (16 U.S.C. 1531 et seq.; 87 Stat. 884), as amended, and the Federal Power Act (16 U.S.C. 791-828c et seq.; 41 Stat. 1063), as amended, and other authorities mandating our concern for environmental values.

GENERAL COMMENTS

We appreciate the document's candor in highlighting each alternative and noting those areas in which the alternative is or may be inconsistent with the requirements of Section 10 of the Endangered Species Act or current science and technology. Obviously, these inconsistencies are problematic for the NMFS and will require resolution before a final decision regarding permit issuance can be made. The Department fully supports the document's strategy of encouraging reviewers to comment on these inconsistencies and suggest potential solutions. Accordingly, these comments focus on those areas of the DEIS that do not adequately address or analyze the potential consequences of permit issuance on areas of special interest to the Department. These areas include the effect of the proposed action on Indian reserved rights and resources that are

subject to the Federal trust responsibility, and Columbia River bull trout, a listed threatened species for which consultation with the U.S. Fish and Wildlife Service may ultimately be required. We also provide comments regarding the need to modify certain terms of the HCPs to reflect current science and technology and align those plans with the requirements of the Endangered Species Act.

In the DEIS, NMFS discusses three alternatives including the proposed action. Alternative 1 is the "no action" alternative and describes baseline conditions and existing regulation of mid-Columbia operations. Alternatives 2 and 3 utilize different sections of the ESA to protect and recover fish species under the Act. Under Alternative 2, NMFS would enter into Section 7 consultations with the Federal Energy Regulatory Commission (FERC) and could require modifications of the projects' federally-licensed operations to protect and recover the listed stocks. Under the proposed action, Alternative 3, NMFS would issue 50-year incidental take permits for the affected species pursuant to conservation plans developed by the project operators and implemented under Section 10 of the ESA.

Tribal Resources and Federal Trust Responsibility

Overview of the Proposed Action's Trust Deficiencies

The projects at issue in this DEIS are located on the mid-Columbia River near lands that were aboriginally occupied by the Tribes of the Columbia River Basin, and the existence and operation of these projects impact and restrict the treaty-confirmed property rights of these and other Indian Tribes. In 1855 treaties with the United States, four Columbia Basin Tribes ceded millions of acres of land while specifically reserving the Basin's fisheries for cultural, ceremonial, subsistence and economic purposes. As the primary Federal agency responsible for protecting the trust property of Indian tribes, the Department has a strong interest in ensuring that these projects are operated in a way that protects tribal trust resources, and specifically, the anadromous fish of the Columbia River Basin.

USDOI

1 The Department is primarily concerned that many of the elements of the DEIS's proposed action, Alternative 3, would impair the ability of the Federal government to fulfill its trust responsibilities to the Columbia Basin Indian Tribes. To protect the Tribes' rights to their treaty reserved property and to avoid liability for a breach of the Federal government's trust obligations, it is essential that NMFS's management role in the basin ensures the maintenance and utilization of the reserved fisheries.

However, pursuant to Alternative 3, the Federal government's responsibility to manage mid-Columbia trust resources would be impermissibly transferred to non-federal entities who are not accountable for breaches of Federal trust and treaty obligations. The decision-making process described in Alternative 3 for implementing recovery measures severely constrains Federal authority. Under Alternative 3, the species' recovery and the management authority of the United States is relegated to Coordinating Committees which yield ultimate decision-making authority to

the non-federal commercial operators. Consequently, NMFS's role in the management of the mid-Columbia fisheries, including treaty trust fisheries, would be reduced to recommending mitigation
1 measures that the Coordinating Committees may reject. Despite the fact that its management authority would be severely constrained, the United States would still be liable for a breach of its trust responsibility should measures under Alternative 3 fail to recover the endangered fisheries.

Given the potential liability, NMFS should require actions that are able, on a sound scientific basis, to protect the endangered fisheries in exchange for the proposed incidental take permits that would be issued under Alternative 3. However, a recent quantitative analysis performed by NMFS to assess the conservation measures included in the proposed action concluded that "[e]ven under the most optimistic scenarios modeled regrading future survival rates and the effectiveness of supplementation, additional survival improvements beyond those projected for the draft HCP action [discussed in this DEIS] would be necessary to achieve extinction risk/recovery criteria." *See* NMFS, *Upper Columbia River Steelhead and Spring Chinook Salmon Quantitative Analysis Report*, Final Technical Review Draft, page ii (December 20, 2000) (*QAR Report*). Moreover, in the context of operations and planned conservation for the entire Columbia River system, the *QAR Report* determined that, "[t]he combined effect of meeting the HCP objectives at the mid-Columbia PUD projects and meeting the off-site mitigation targets [for the rest of the Columbia River] would be substantial but would fall short of meeting survival and recovery criteria under the assumption that 1980-present conditions will continue." *QAR Report* at iii. Thus, according to NMFS's own best science, whether the DEIS's proposed action does enough to protect trust resources is questionable.

In contrast, the provisions of Alternative 2 maintain the Federal government's and NMFS's trust responsibility role while providing NMFS with the authority to ensure a full range of measures to protect and ensure the continued existence of endangered mid-Columbia trust resources. In light of the constraints that Alternative 3 would impose on the United States' ability to manage resources subject to its trust responsibility to the Columbia Basin Tribes, and given the scientific uncertainties identified in the DEIS regarding the implementation of Alternative 3, the Department is gravely concerned about the merits of issuing 50-year incidental take permits under the terms described in the DEIS's proposed action. We offer the following comments in support of these concerns.

<u>The Proposed Action Impermissibly "Transfers" NMFS's Federal Trust Responsibility to Non-Federal Entities</u>

The DEIS's proposed action, Alternative 3, impermissibly transfers the Federal government's authority to ensure the maintenance and utilization of Indian trust resources to two non-federal entities, the PUDs, operating projects on the mid-Columbia. Under Alternative 3, NMFS would be subject to an implementation process that gives ultimate management authority to project operators for the 50-year term of the incidental take permits. Pursuant to the three phase decision-making process described in Alternative 3, NMFS would be unable to initiate recovery measures and would be subject to the ultimate decision-making authority of the project operators.

Moreover, should NMFS disagree with a project operator about recovery measures, NMFS would be required to carry the burden of proof in a dispute resolution process with time and
2 evidentiary limitations. By constraining and transferring NMFS's authority to manage threatened trust resources, Alternative 3's implementation process is contrary to common trust principles and may expose the Federal government to liability for failing to sufficiently manage and protect the Tribes' treaty-reserved resources.

As described in the DEIS, Phase I of this three-phase process requires NMFS to transfer its authority to manage the plan species to the project operators themselves. During this time, the PUDs will attempt to modify project operations to attain 91 percent overall project survival and
3 95 percent juvenile passage survival at each project. According to Alternative 3, a Coordinating Committee will be formed to ensure that the project operators are making "steady progress" toward survival goals.[1] This Coordinating Committee can recommend "parallel actions" to the project operators. *See* DEIS at 2-35. However, if a Coordinating Committee is unable to reach consensus as to mitigation procedures, or even whether a project is meeting survival standards, the project operators themselves are provided the "ultimate authority" for final decision-making under the Coordinating Committees. *See* DEIS at S-19 and 2-53.

If after five years the project operators are unable to attain the survival goals set forth in Alternative 3, the implementation process moves to Phase II. During this phase, the Coordinating Committee will evaluate the mitigation measures that were utilized by the project operators and may recommend additional measures to ensure that survival goals are achieved. NMFS, as a member of the Coordinating Committee, will be able to participate at this stage in the process and may recommend more stringent mitigation tools. However, if the Coordinating Committee is unable to reach consensus as to these additional measures, the project operators will retain the ultimate authority to determine the necessary mitigation measures unless a dissatisfied member of the Coordinating Committee is willing to submit itself to the dispute resolution process. *See* DEIS at 2-53.

Pursuant to Alternative 3's dispute resolution process, if NMFS desires to oppose a decision of the Coordinating Committee or to oppose the continued use of the project operators' mitigation tools, NMFS will be required to prove by a preponderance of the evidence that the operators' mitigation measures are insufficient. If NMFS purports that the mitigation provisions violate the ESA, NMFS must also overcome a presumption that favors the existing mitigation measures.[2] The expertise of NMFS will receive no deference in the dispute resolution process, and NMFS

---

[1] This Coordinating Committee will be comprised of representatives of each signatory party. DEIS at 2-36. Because the Tribes have been unable to agree to the terms of the existing HCPs, and are not expected to be signatory parties, the Tribes will not be represented on this Committee.

[2] This is a presumption expressly built into the dispute resolution process and, more generally, the DEIS asserts that because Alternative 3's measures are consistent with "HCP agreements and protocols" by definition they cannot violate the ESA. *See* DEIS at S-17.

will have only five months to prove that the PUDs' mitigation tools are insufficient. Under such a dispute resolution process, NMFS's ability to ensure that trust resources are protected is severely constrained.[3]

Finally, if any of the project operators are able to demonstrate that they are meeting survival standards, the implementation process enters Phase III. Pursuant to Phase III, the three hydroelectric projects will be subject only to periodic review to assess whether they are meeting
4 Alternative 3's survival standards. During this phase, NMFS will not be able to require any additional mitigation actions. Even if, years later, the plan species require additional protective measures, Alternative 3 precludes NMFS from imposing such measures. Consequently, for the 50-year term of the HCPs NMFS's Federal responsibility and ability to ensure the survival and utilization of endangered trust resources is effectively and impermissibly transferred to non-federal parties.

The Tribes of the Columbia Basin will be depending on NMFS to ensure adequate protection of the river's tribal trust resources. If NMFS, pursuant to Alternative 3, is required to transfer its
5 management authority to project operators, which are private commercial entities, NMFS would be violating its trust responsibility to the Tribes and perhaps exposing the Federal government to liability for failing to properly manage treaty-reserved resources.

Moreover, the DEIS fails to discuss the implications that Alternative 3 has on NMFS's obligation to manage the mid-Columbia's resources in the best interests of the Columbia Basin Tribes. While Alternative 3 would displace NMFS's role as trustee for the Tribes' reserved fisheries, the
6 DEIS provides no general or specific discussion regarding the potential consequences or impacts that may result from this "transfer" of management authority of treaty reserved resources to non-Federal parties, or indeed, whether such a "transfer" is legally permissible.

In contrast, the provisions of Alternative 2 would allow NMFS, BIA, FWS, the Tribes, and all other interested stakeholders to consult with and/or appear before FERC to ensure that the
7 federally-licensed project operations account for the United States' trust responsibilities. Under the provisions of Alternative 2, NMFS would engage in Section 7 consultations with FERC and would retain the authority and responsibility to ensure that the projects' federally-licensed operations are consistent with the biological needs of the endangered trust resources. For example, Alternative 2 includes a range of specific recovery actions that NMFS has determined are necessary to improve biological conditions for the affected species, but not all of these actions

[3] The Department is concerned that the dispute resolution process has already proven to be an unsuccessful mechanism to protect trust property or to carry out the Federal government's trust responsibility. Specifically, the BIA notes that the project operators have been operating under the terms of the HCPs since 1998 and have been utilizing the dispute resolution process since then as well. Several disputes have arisen over the last three years, specifically disputes regarding timing and quantity of migration spill. The PUDs, Chelan in particular, have basically ignored the dispute resolution process and have made unilateral decisions on how to proceed on these issues despite repeated requests from NMFS and the Tribes. Such a track record does not bode well for future cooperation on implementing discretionary measures under Alternative 3.

are included in the measures proposed under Alternative 3. *See* DEIS at 1-14 to 1-16. Of the alternatives presented, only Alternative 2 ensures that NMFS is able to completely and responsibly fulfill its role as trustee for the treaty-reserved resources of the Columbia Basin Tribes. Accordingly, the Department maintains that NMFS should utilize the procedures described in Alternative 2.

The DEIS and the Proposed Action do not Adequately Consider Impacts on the Tribe's Treaty Reserved Fishing Economies

8 The DEIS's analysis of the proposed action's likely impacts on the Tribes' reserved harvests is inadequate and in key respects, absent. In place of such an analysis, the *QAR Report*, which assesses the survival and recovery requirements of listed upper-Columbia steelhead and spring chinook salmon, supposedly considers treaty harvests. However, harvest was modeled in the *QAR Report* under the assumption that recent harvest rates would continue into the future. The effect of assuming that treaty harvest rates for spring chinook would remain at the extremely low levels of the past two or more decades is that the adequacy of Alternative 3's project passage and
9 survival goals are overstated. While the DEIS, through the *QAR Report,* recognizes that additional survival gains will be needed, Alternative 3 does not examine the relationship between these additional survival needs and the needs of treaty harvest. The unfolding experiences of the 2001 drought indicate that it may not be prudent to assume that non-project survival would be stable, let alone improve for Upper Columbia listed stocks.

Had the DEIS accounted for the protection and recovery of the Tribes' trust property, the reasonableness and necessity for additional tribal conservation of the listed species would have been carefully analyzed, not assumed. In these circumstances, NMFS's analysis should
10 demonstrate that such conservation could not be achieved by reasonable regulation of non-Indian activities. It is not clear that the alternatives in the DEIS were ranked in their ability to achieve the required conservation purpose. Absent this ranking, an alternative may be selected that discriminates against future Indian harvest necessitating conservation measures the Tribes are not voluntarily willing to accept. Joint Secretarial Order 3206 states that when ESA listed species affect the exercise of tribal rights, the Department and NMFS will cooperate with affected tribes to develop and implement recovery plans in a manner that minimizes the social, cultural and
11 economic impacts on tribal communities, consistent with the timely recovery of listed species. The DEIS acknowledges that Alternative 3's proposed conservation measures were completed without the benefit of such tribal cooperation. Secretarial Order 3206 pledges the Services to working cooperatively with tribes to identify and implement the most effective measures to speed the recovery process. Alternative 3 neither identifies the actions needed to assure a speedy recovery, nor guarantees that such actions would be implemented.

Consequently, Alternative 3 is problematic due to its potential impact on the Tribes' treaty reserved harvests of mid-Columbia fisheries. The listing of ESA salmon populations which spawn
12 upstream from the subject projects currently restricts harvest in treaty fisheries at treaty reserved usual and accustomed fishing sites. This restrictive effect is detailed in the NMFS's 2001

Biological Opinion for spring and summer treaty harvest. *See* NMFS, *Biological Opinion, Impacts of the Interim Management Agreement for Upriver Spring Chinook, Summer Chinook and Sockeye on Salmon and Steelhead Listed Under the ESA* 2001. The DEIS does not quantitatively describe Alternative 3's future effects on harvest. This is especially important in light of the ramifications of underestimating ESA-permitted mortality of listed salmon. The cumulative effects of such underestimation have two predictable consequences -- dangerously low numbers of returning adult salmon and the continued curtailment of tribal fisheries. The hatchery mitigation component of Alternative 3 does not address this situation if present hatchery policies yield an incomplete replacement of wild fish killed by the PUD projects.

Furthermore, the DEIS generally does not consider the range of issues related to NMFS's trust responsibility to ensure the utilization of fishery resources reserved by the Tribes. For example, in
13 Section 3.7 of the DEIS, "Socioeconomics - Population, Employment, and Income," NMFS mentions the tribal population of the region, but fails to account for the impact of mid-Columbia of projects on the Columbia Basin Tribes' fishing economies. While the DEIS notes that in at least one county impacted by the projects "Native Americans constitute an important part of the County economy," there is no general or specific discussion of the projects' economic impacts on the Tribes' commercial and subsistence fishing economies. *See* DEIS at 3-132. Rather, the DEIS merely discusses project benefits to industry, tourism, and agriculture without contrasting these perceived benefits in light of the substantial detrimental impacts on the Tribes' fishing economy for which NMFS is a trustee.

A recent study assessing the economic impacts of the mid-Columbia projects found that tribal harvests on the mid-Columbia have dropped to less than 10 percent of traditional harvests. *See*
14 CH2MHILL, *Human Effects Analysis of the Multi-Species Framework Alternatives* 3-6 (1999) (prepared for the Northwest Power Planning Council). In addition, specifically assessing the broad social impacts on the Tribes, the study notes that such an economic and cultural loss powerfully impacts the material well-being and self-sufficiency of tribal members and negatively affects physical and psychological health. *Id.* at 3-7. Given NMFS's role as a Federal trustee, and considering that Native Americans constitute 11 percent of the population for one of the counties under discussion, it is incumbent on NMFS to weigh the impacts of the proposed action on the tribal fishing economies. Moreover, as the DEIS notes the region's depressed economy, NMFS should also include in its economic discussion the ways in which a profitable and self-sustaining salmon harvest could increase tribal self-sufficiency, alleviate unemployment and poverty, and improve the region's depressed economy. *See* DEIS at 3-130.

In passing, we note that the economic impacts that are not fully discussed in the DEIS have far-reaching consequences not only on the Tribes, but on non-Indians as well. The CH2MHILL
15 study also reported that the non-Indian catch has fallen to less than 1 percent of commercial catches in 1900. *See* CH2MHILL, Human Effects Analysis of the Multi-Species Framework Alternatives 3-6 (1999) (prepared for the Northwest Power Planning Council). The economic benefit of the power projects, as well as their economic detriments, need to be fully displayed in the DEIS.

The 50-Year Term of the Proposed Action is Inappropriate for the Management of Riverine Ecosystems Supporting Trust Resources

16 In light of the Federal government's trust responsibility and the dynamic ecological conditions of the Columbia River, the Department believes it is inappropriate and risky to constrain the Federal government's authority to manage endangered riverine species for the 50-year term of the proposed action. We strongly believe that the proposed action would be greatly improved by matching the term of the HCP with the licensing authority of FERC. Therefore, we recommend that if NMFS decides to issue incidental take permits for these projects, the permits should be for no longer than the term of the existing FERC licenses. Subsequent licenses could include identical provisions of the HCPs, if the HCPs are operating to protect and ensure the continued existence of endangered mid-Columbia trust resources.

17 Under Alternative 3, NMFS would issue incidental take permits that establish the measures through which the species' losses can be mitigated. As proposed, the HCPs would contain the only mitigation measures that NMFS would recommend to be employed for the next 50 years. The practical effect of a NMFS decision to select Alternative 3 is to predetermine the extent of the recovery measures at relicensing and to impose conditions on subsequent licenses many years before the relicensing process. This would seriously undermine the relicensing process and is beyond the scope of FERC's authority to implement.

18 The purpose of relicensing is to evaluate the hydropower project under the environmental conditions occurring at the time of licensing and to determine what changes are necessary to ensure the protection of important public resources into the future. As such, FERC regulations require the licensee to undertake a complete revaluation of their project and the impact on natural resources, water quality, recreation, flood control, navigation, power production, and many other factors. This would occur regardless of whether NMFS issues an HCP. Therefore, at the time of relicensing, there will be a complete reevaluation of the project and a considerable amount information in the administrative record outlining the continuing impact of the project on important fish and wildlife resources, including listed species. It is possible that the information may indicate unacceptable levels of impacts to listed species, or that the mitigation measures are ineffective. If NMFS issues an HCP for 50 years, they may find themselves in the difficult position of recommending mitigation measures that have been shown to be ineffective, counter-productive, or wasteful. The Department strongly believes that perpetuating such mitigation is not in the public interest, particularly when the relicensing process is intended to correct such problems.

19 The proposed action's 50-year time frame is especially problematic in light of the "no surprises" policy set forth in regulations implementing Section 10 of the ESA. The "no surprises" regulations were adopted to provide long-term assurances to landowners by allowing them to avoid additional mitigation measures during the term of an incidental take permit. However, constraining the Federal government's ability to protect listed species in the mid-Columbia River

for the next 50 years is inappropriate for the management of a fragile river habitat, particularly since it exceeds FERC's authority, and the action directly affects habitat that supports important Federal trust resources and treaty reserved fishing rights. Unlike private lands, the Columbia River is a public waterway and its biological health is essential to many stakeholders, including the Tribes of the Columbia River Basin.

The proposed action is especially troubling in light of FERC's responsibilities under section 7 of the ESA. When a listed species is affected by project operations, FERC is required to consult with NMFS (or FWS) pursuant to section 7 before issuing a new license. Such consultation usually results in a biological opinion that specifies the ways in which a project can be operated to avoid jeopardizing listed species. However, if NMFS selects Alternative 3 of the DEIS, NMFS may be unable to require FERC to include mitigation measures that go beyond those provided in Alternative 3. This would occur despite the possibility that substantial information may be in the record indicating significant impacts to listed species are occurring and may continue to occur with any new license issued. Consequently, by committing to the terms of Alternative 3 prior to section 7 consultation with FERC, NMFS effectively precludes the inclusion of additional mitigation measures in a subsequent FERC license, even though there may be substantial information indicating such measures are needed.

20

This is particularly problematic because the Wells' license will not expire until 2012 and Rock Island's current license will not expire until 2028. Thus, even if salmon and steelhead populations dramatically decline over the next several years, because of the projects' incidental take coverage under Alternative 3, NMFS may not be able to recommend additional mitigation measures for unavoidable mortality in any subsequent licenses. The effect of limiting additional mitigation measures is that under poor environmental conditions, there becomes an "over appropriation" of mortality with impacts on trust resources via otherwise avoidable fishery restrictions. Consequently, in contrast to the requirements of Secretarial Order 3206, the proposed action's use of the "no surprises" policy and its effect on FERC licensing may subject tribal use of treaty trust fisheries to long term diminishment depending on climatic conditions or improvements elsewhere in the Columbia Basin.

21

Instead, we suggest that NMFS limit the length of the incidental take permits to the term of each project's existing FERC license. By matching the length of the incidental take permits with limits of the FERC license, NMFS aligns their actions with FERC's authority plus they maintain the ability to revisit the HCPs' at relicensing. As such, NMFS would be able to ensure that, in the unlikely event that these mitigation measures are unsuccessful at protecting listed species as NMFS and the licensees expect, each new license could contain provisions that adequately protect endangered trust resources. Conversely, if the HCP is operating as NMFS and the licensees expect, we would not expect NMFS to recommend any further changes at relicensing. Under these circumstances, the provisions of the HCP could continue through the next licensing period. We believe this would be consistent with the "no surprises" policy.

22

In addition, we suggest that NMFS incorporate some of the provisions of Alternative 2 into its proposed action. Under Alternative 2, the project operators would seek new FERC licenses
23 pursuant to the Federal Power Act and FERC would consult with NMFS pursuant to section 7 of the ESA. It is current FERC policy to routinely insert re-opener clauses into new licenses which allow FERC to reconsider fish and other natural resource issues, if warranted. Thus, under Alternative 2, FERC and NMFS would be able to ensure that the projects would be operated in a way that is responsive to trust fishery needs. This is particularly important in a ecosystem as dynamic as a river basin, where aquatic species populations constantly fluctuate in response to the quality and quantity of water and habitat conditions.

Fish and Wildlife Resources

HCP Performance Standards

As the DEIS notes, both the NMFS and the U.S. Fish and Wildlife Service recommend that biological goals and objectives be incorporated into HCPs. The 95 percent juvenile dam passage
24 survival standard and the 91 percent total project survival standard incorporated into Alternative 3 (the proposed action) are examples of biologically-based standards. The 95 percent standard limits the direct mortality of dam passage while the 91 percent total project standard is intended to limit losses in the total project area, including the dam and reservoirs. We note, however, that actual total project mortality is a combination of direct and delayed adult and juvenile mortality attributable to project effects. Delayed mortality can and does occur outside the project area. Many fish are injured as they pass through the pool above each dam and the tailrace below each dam, but do not die until they are past the project boundary. Subsequently, by limiting the application of the 91 percent total project survival standard to the immediate vicinity of the dams, Alternative 3 fails to account for a potentially significant amount of incidental take. The issue of delayed mortality (project-related mortality occurring outside of the project area) needs to be addressed in greater detail. If necessary, the components of the total project survival standard should be reevaluated to be certain that all forms of project take are fully considered.

The *QAR Report* indicates an improved potential for in reach survival for spring chinook salmon
25 and some increase in the probability of meeting recovery criteria if Alternative 3's survival standards are combined with expected survival improvements at lower Columbia River Federal dams contingent upon environmental conditions observed since 1960. However, the ability of steelhead to meet recovery criteria is more problematic and is dependent on assumptions concerning the effectiveness of hatchery supplementation and whether environmental conditions would be similar to those seen since 1960. Although no one can predict exactly what future conditions might be, using a long term database should more accurately reflect a full range of environmental possibilities.

The QAR modeled a range of different survival (including the survival standards proposed in the HCPs), passage, and environmental conditions that could reasonably be expected to occur in the future. If met, the standards identified in Alternative 3 should offer improvements in long term survival for all plan species as compared to the current situation. Although the *QAR Report* did not model potential survival for species other than steelhead and spring chinook salmon, we expect that survival benefits would also accrue for sockeye, summer/fall chinook and coho as a result of the survival standards and mitigation.

An example of the improvement expected with Alternative 3 compared to Alternatives 1 or 2 would be the benefits accrued for non-listed sub-yearling summer/fall chinook by application of the survival standards during the summer juvenile migration at Rock Island Dam. Spill is the primary juvenile summer passage measure at this project, but the amount and duration of spill is based on the dollar value of the Conservation Account which is a component of Alternatives 1 and 2. As energy prices and demand rise, the spill program provides less fish protection over the summer period. Since summer migrants are not ESA listed species (with the possible exception of bull trout), the Conservation Account is the only passage measure providing assured protection for these fish. The limited protection inherent in the Conservation Account does not apply to Alternative 3. The HCP standards must be met regardless of the yearly cost of energy and are not limited by a predetermined dollar amount. In addition, Alternative 3 provides an increased level of juvenile fish protection because the 95 percent juvenile dam passage survival standard applies over 95 percent of the run. This likely provides more protection than juveniles currently receive via Alternative 1 spill and bypass programs at Rock Island Dam and Rocky Reach Dam for all plan species. It also provides improved passage benefits for summer migrants, not necessarily assured by Alternative 2. The current spill/bypass program at Wells Dam appears to be providing protection over 95 percent of the run for all species.

The Department interprets Alternative 3 as indicating that for all plan species, the HCP standards must be met regardless of the yearly cost of energy or drought. In addition, the projected improvements at the lower Columbia projects must not be impacted by cost or drought. If that is not the case, then the QAR analysis may be inadequate in modeling the future effects of this alternative. The FEIS should clarify this aspect of Alternative 3 and the QAR analysis. In addition, the DEIS should include data on the level of improvements needed to sustain tribal harvests well above recent severely restricted levels. Alternative 3 does not examine the relationship between additional survival needs and the needs of treaty harvests.

Verification of Standards

26 Verifying the biological standards of Alternative 3 would be of critical importance in determining whether this alternative actually meets its stated goal of no net impact (NNI) and contributes to the recovery of anadromous salmonids. Achieving and maintaining these survival standards is the element necessary to allow NNI attainment through hatchery compensation (7%) and tributary habitat improvements (2%).

Unfortunately, direct measurement of total project survival (91% standard) is not technologically feasible at this time. This is acknowledged in the DEIS. Key problems are estimating survival for subyearling summer/fall chinook (the primary fish migrating during the summer period), measuring juvenile sockeye spring migration survival, identifying project related adult survival independent of other non-project related impacts, and measuring cumulative indirect impacts for adults and juveniles. Moreover, Alternative 3 does not even attempt to measure adult mortality. Finally, the effect of delayed mortality on the ability of Alternative 3 to protect trust resources also remains to be clarified. These measurement problems exist for all alternatives, but under
27 Alternative 3, compensation programs may be adjusted up or down based on these survival studies.

The DEIS recognizes these problems but offers only the use of some indirect methods
28 ("representative survival studies") to assess survival and indirect losses. Such representative studies are an unacceptable way to measure the survival of all the species affected by the projects, species that contribute to treaty fisheries. Additionally, these "representative studies" are less likely to assure the broad protections that the DEIS claims because they do not measure all of the affected species at a variety of life stages and flows. Given these uncertainties, Alternative 3 cannot be considered to be protective of treaty trust fisheries unless it includes an established scientific methodology for measuring fish survival.

If the survival standards cannot be fully verified, the size of compensation programs necessary to
29 reach NNI cannot be fully identified. Until the uncertainty surrounding measurement of total project survival is resolved, it may be appropriate to develop an interim measurable standard such as 93 percent juvenile total project survival before moving to Phase 3 and triggering adjustments in hatchery/tributary compensation levels down from the 7 percent and 2 percent levels. Allowing a reduction in compensation without appropriate verification or an approved alternative would not be consistent with the intended goals of Alternative 3.

Adjusting Compensation

The DEIS notes that dam and project juvenile survival has been measured for the Douglas PUD project for steelhead, spring chinook, and fall chinook yearling migrants. These evaluations have
30 occurred over the spring migration season in one or several years, but have not occurred over the range of conditions that are expected to occur from year to year. According to the DEIS, Douglas PUD hopes to adjust its hatchery compensation levels and tributary habitat fund proposed in its HCP utilizing the survival studies that have been done to date. We surmise that Douglas PUD would adjust the hatchery component for steelhead and spring chinook salmon below the 7 percent compensation level based on these spring migration survival studies coupled with other indirect survival measurements. Given that under Alternative 3, total project survival is not based just on juvenile survival, we find it difficult to support reducing hatchery compensation levels below the 7 percent level for a species without a process to address at least some of the other uncertainties. As noted previously, this leaves Alternative 3's goal of NNI without any verifiable method of validation. In addition, we have concerns about reducing the tributary fund

component (2%) without a more systematic approach to defining what actual survival is occurring. Such a reduction of compensation without an agreed upon way of verification is inconsistent with the government's trust obligations to the Columbia Basin Indian Tribes and the goals and objectives of Alternative 3.

31 One means of correcting this inconsistency would be to revise Alternative 3 to preclude a reduction in hatchery compensation and tributary habitat improvement below the 7 percent and 2 percent levels without agreement on the appropriate measurement criteria for these critical uncertainties by the mid-Columbia Coordinating Committee or some similar technical group. It would be essential for tribal issues regarding the proposed action to be overcome and for the Tribes to be active participants in plan implementation. Alternatively, the total project survival standard could be revised to an interim juvenile total project survival standard of 93 percent. Measuring juvenile project survival is something that can be accomplished with current methods and technology. Once a method of measuring adult survival and indirect juvenile mortality is available, the total project survival standard could return to the 91 percent level and compensation levels adjusted as described in Alternative 3. Lastly, we note that Alternative 3 does not clearly indicate that achieving and maintaining the survival standards for one plan species does not mean that the survival standards have been reached for all plan species. Use of yearling chinook and/or steelhead as surrogates for doing survival studies of sockeye and subyearling chinook is not appropriate for these fish which demonstrate different behaviors and life histories. No reductions in compensation levels should occur for any plan species where components of the total project survival standard are unknown. It is hoped that full consideration of these suggested modifications will lead to an acceptance of the HCPs by all parties.

Maintaining 7 Percent Hatchery Compensation

32 ESA issues related to the potential impacts of hatchery supplementation on wild productions have the potential to limit attainment of the 7 percent hatchery compensation level, the goals for the recovery of listed species, and NNI. This is identified in the DEIS as a significant unresolved issue with respect to Alternative 3. This impact also has a direct bearing on the results of the QAR analysis and selection of the most appropriate alternative. For example, if hatchery steelhead are just as effective reproductively as wild fish, then Alternative 3 would not meet conservation criteria under any scenario. Additionally, the constraints imposed by the ESA also limit the potential expansion of hatchery programs to meet compensation requirements and NNI needs. These constraints include the potential short and long term negative genetic, behavioral interaction, and spawning fitness impacts of hatcheries and supplementation on the viability of naturally spawning populations of listed fish. These issues relate to all three alternatives, but most severely effect the potential expansion of hatchery production in Alternative 3 to reach NNI.

The DEIS states that NMFS can not commit to the 7 percent hatchery compensation goal. Because of NMFS concerns that hatchery fish may adversely affect wild fish populations, all fish produced from the hatchery program must come from local stocks. *See* DEIS at 2-43. The DEIS acknowledges that it will be difficult to produce the number of fish needed to ensure 7 percent

compensation from local stocks alone. *Id.* Lastly, the DEIS states that "if the 7 percent hatchery compensation level is not met due to NMFS's ESA concerns, neither the dam passage survival standard, the total project survival standard, nor the habitat compensation standard would be
32 adjusted." DEIS at 2-43. Consequently, reliance on Alternative 3's hatchery programs to compensate for the incidental take of listed species is problematic.

While we recognize that NMFS's concern with hatchery supplementation programs applies to all the alternatives considered in the DEIS, hatchery compensation is a significant factor for Alternative 3 because it is wedded to the attainment of NNI. Erosion of the hatchery compensation provisions of Alternative 3 would prevent NNI from being achieved. More so, given the absence of provisions in Alternative 3 to compensate for take through other means if the hatchery programs fail to produce the number of fish necessary to meet the 7 percent hatchery compensation standard. Furthermore, hatchery compensation is significant in light of the fact that the Columbia Basin Tribes have reserved the right to harvest the affected species. These Tribes have already faced significant restrictions in tribal harvest caused by the status of listed stocks, and a disconnection of the hatchery compensation program from continued losses of wild fish to the projects can only result in additional harvest restrictions.

Columbia River salmon and steelhead constitute important tribal trust property, and the right to fish at usual and accustomed fishing sites on the Columbia River, and to have a meaningful fishery there, is a property right that is protected through treaties with the Federal government. The mid-Columbia's stocks of salmon and steelhead are being depleted at alarming rates, and the ESA has forced the Federal government to seek severe restrictions on the number of fish available for tribal harvest. If the river's stocks continue to decline, the Tribes may face even tighter restrictions. Hatchery production is critical to the on-going harvesting needs of Tribes of the Columbia River Basin. Consequently, it is imperative that the hatchery compensation provisions of the selected alternative assure that there would be mitigation to fully compensate for the treaty fish lost through incidental take.

The effectiveness of hatchery compensation as a tool for achieving NNI might be strengthened by including in the HCPs studies to evaluate the effects of hatchery supplementation on the viability and restoration of self-sustaining, natural populations of salmon and steelhead. This should be done at a selected site or two in the upper Columbia River with an existing or new supplementation effort. We also recommend the Bonneville Power Administration(BPA) as a potential funding source because this issue is common to all supplementation programs, and BPA is funding offsite mitigation measures associated with operation of the Federal Columbia River Power System (FCRPS). Such a study would start answering uncertainties related to genetic interaction and reproductive fitness issues that are a major source of contention. These recommended studies are critical to recovery efforts, full mitigation compensation, and in satisfying the harvest needs of the Tribes.

Tributary Conservation Plan

33 Under Alternative 3, 2 percent of the fish lost through incidental take at each project would be compensated for through tributary habitat restoration. Tributary habitat restoration is a significant component of Alternative 3 because it is wedded to the attainment of NNI. The proposed action, however, does not provide for the monitoring of tributary contributions to ensure that this percentage is met. In addition, it is acknowledged that the 2 percent tributary compensation standard is a negotiated figure. This figure is not based on scientific analysis which predicts that tributary restoration would result in increased tributary compensation. Instead, this
34 figure is based upon the level of funding that the project operators are willing to set aside for tributary habitat restoration. The DEIS assumes that attainment of the 2 percent compensation level is reasonable because the selection of restoration projects would be controlled by a technical committee. If this assumption proves optimistic, there are no provisions in Alternative 3 that allow for this contribution to be increased or for other restoration measures to be implemented. Hence, the reliance on tributary habitat restoration to compensate for the incidental take of listed species and achieve NNI is problematic.

The DEIS acknowledges that there are "difficulties and uncertainties associated with monitoring and quantifying the effects of tributary habitat improvements." DEIS at S-18. The DEIS does
35 not propose a way to overcome these "difficulties and uncertainties" and construct a standard by which the percentage of tributary compensation would be accurately measured. The risk that NNI may not be met if the assumed benefits of habitat restoration are not realized must be fully disclosed. Still, disclosure of this risk is not a substitute for the mitigation of potential impacts on trust resources. At the very least, the FEIS should explain how Alternative 3 meets the criteria for issuance of an incidental take permit in the absence of a viable method for confirming tributary contributions to NNI or, lacking a measurable standard, a clearly specified alternative strategy for achieving this 2 percent compensation level.

We also note that Alternative 3 apparently limits the compensation that may be achieved through
36 habitat restoration by shifting the focus of habitat restoration activities to the tributaries and away from the mainstem river. The DEIS makes numerous references to locations where active mainstem spawning is occurring. While the mid-Columbia projects ultimately limit mainstem habitat productivity, these pockets of mainstem spawning habitat within the project boundaries provide models for increasing spawning and rearing habitat within the mainstem river. Therefore, mainstem habitat restoration should be considered to be within the scope of the this alternative's tributary habitat improvement program. Taking steps to conserve and protect existing mainstem spawning habitat should not be overlooked as a potential means of minimizing the impact of incidental take.

Water Quality and Water Temperature

37 Alternative 3 acknowledges that the Wells, Rocky Reach, and Rock Island Projects negatively impact water quality, and, most particularly, dissolved gas levels. The proposed action fails to

address mitigation of these negative impacts other than to indicate that the PUD's would meet state standards for water quality. Because spill appears to be a needed component for fish bypass at each of these projects, avoiding spill does not appear to be a long-term solution to resolving dissolved gas problems. Consequently, the discussion of alternatives in the DEIS should be expanded to include measures to address meeting water quality standards through the installation of gas abatement structures.

38 Water temperature is also a matter of concern. Water temperatures can be high in the surface waters of reservoirs in the Columbia River and in fish passage facilities. Under Alternatives 1 and 2, measures to improve thermal conditions at each project could be pursued through avenues such as FERC relicensing, Clean Water Act compliance, or ESA section 7 consultation. Alternative 3 proposes a specific set of measures to meet the NNI standard of the HCPs. However, the implementation of structural and operational modifications to improve the water temperatures at these dams does not appear to be specifically included. If an incidental take permit is issued incorporating the proposed terms of Alternative 3, the adoption of other measures to improve thermal conditions may be precluded. The FEIS's discussion of Alternative 3 should be expanded to include plans to monitor water temperature and, if problems are observed, implement structural and operational modifications to improve thermal conditions at these projects.

Bull Trout

39 The DEIS correctly acknowledges that bull trout occur in the mid-Columbia reach where the PUD projects operate and presents information from most available sources. Information on the distribution of bull trout in the mid-Columbia River area is limited. However, additional information may be available to augment the information presented in the DEIS. PUD ladder counts have noted the presence of adult bull trout for many years. The recent listing of bull trout has prompted additional vigilance at these counting stations during in the last two years. The PUDs have also recently initiated a research effort aimed at tracking the movements of bull trout in the Columbia River. Hence, additional recently developed information may be available. Other sources of information include the Washington State Salmonid Stock Inventory for bull trout/dolly varden.[4] With this information in hand, a more complete analysis by NMFS of the effects of permit issuance and HCP implementation on bull trout can and should be incorporated in the FEIS.

40 The effects of hydropower operations on bull trout in the mid-Columbia River are not specifically known, as indicated in the DEIS, but inferences may be suggested by comparing what is known about bull trout behavior and distribution with the effects that have been described for bull trout and other salmonids at other Snake and Columbia River hydropower projects and associated reservoirs (see the December 2000 NMFS and Fish and Wildlife Service biological opinions on the FCRPS operations). These effects include entrainment, turbine-associated mortality and

[4] Washington Department of Fish and Wildlife. 1996. Washington state salmonid stock inventory: bull trout/dolly varden. Draft Report.

injury, passage delays, habitat alteration, stranding, reduced prey base, and associated adverse effects on individuals and discrete populations. The effects of hydropower project operations on adult steelhead may be especially analogous to those affecting adult bull trout, as both species have the potential to migrate downstream as well as upstream (although fluvial bull trout generally survive spawning and return to the mainstem river as a rule, while this may be the exception for steelhead).

40

Except for a brief discussion of the potential effects of project operations and HCP implementation on adult migratory bull trout, no inferences are made in the DEIS regarding potential adverse effects on juvenile bull trout. Nor does the DEIS consider conservation measures to minimize the incidental take of bull trout that could be included in the proposed HCPs or stipulated as conditions in NMFS's section 10(a)(1)(B) incidental take permits. As the lead Federal action agency responsible for the development of the DEIS and the proper implementation of the proposed HCPs, NMFS has the primary responsibility to describe the effects of its proposed actions and to avoid or reduce adverse effects on bull trout.[5] Such information should be included in the FEIS.

Pending the development of any new information, bull trout conservation measures that should be incorporated in the HCPs and reflected in the FEIS to reduce potential adverse effects include, at a minimum, those identified in the December 2000 NMFS and Fish and Wildlife Service biological opinions on the FCRPS operations. In the NMFS biological opinion, those measures identified for steelhead are particularly germane to the conservation of bull trout. Implementation of these measures would partially fulfill section 7(a)(1) requirements of the respective Federal agencies, and enhance timely section 7(a)(2) consultation in the future. They are as follows:

- The PUDs should determine the extent of bull trout use of the middle Columbia River affected by the subject hydropower projects. This would include the river reach from the Chief Joseph Dam downstream to Wanapum Dam reservoir. This effort would include recording the occurrence of bull trout in the smolt monitoring facilities at the middle Columbia River dams and their use of adult ladders.

- The PUDs should include bull trout as a species of concern in their research efforts to determine the upstream and downstream passage requirements of salmonids at middle Columbia River dams. These investigations should address entrainment, both upstream and downstream adult passage, and juvenile passage. Consideration of spill, flow attraction, temperature and other issues affecting passage should be included.

- The PUDs should include observations of bull trout captured in field activities under their funding (e.g., research studies and northern pikeminnow reward program fisheries) and

[5] On page 4-48 and elsewhere, NMFS appears to suggest that consultation under section 7 of the ESA regarding the effects of permit issuance and HCP implementation on bull trout is a matter to be resolved between the Fish and Wildlife Service and the FERC.

report that information annually to the Fish and Wildlife Service.

40

- The PUDs should cooperate in studies to determine the movements of bull trout from tributaries into middle Columbia River reservoirs. Include the Service, Washington Department of Fish and Wildlife, Forest Service, and Native American Tribes, whenever appropriate, in development of research/study plans.

- The PUDs should initiate studies to determine the effect of flow fluctuations on river or reservoir water surface elevations and on stranding or entrapment of bull trout and other aquatic life related to the prey base of bull trout.

- Depending on the results of monitoring described above, the PUDs should, in consultation with the Fish and Wildlife Service, consider expanding the fish counting periods to include time periods outside the normal upstream migration periods for adult salmon and steelhead. It is important to note that if bull trout are seldom observed, it may mean they seldom use the fish passage facilities or migrate at different times than salmon and steelhead, and does not necessarily mean they seldom use the mainstem river and reservoirs.

- The PUDs should implement an adaptive management approach for designing and implementing actions, including performance standards, relative to bull trout that are similar to those being developed in the HCP for Permit species (salmon and steelhead).

- The PUDs should include consideration of bull trout in any studies addressing downstream movement of steelhead kelts and any subsequent operational or structural modifications aimed at improving the survival of adult salmonids migrating downstream through the dams.

- The Fish and Wildlife Service recommends that the PUDs participate in implementation (when completed) of the bull trout recovery plan.

Section 7 consultation requirements regarding the effects of implementing the proposed HCPs on listed species may be addressed by NMFS through several pathways: 1) internal ESA section 7 consultation analyzing the effects of issuing section 10(a)(1)(b) incidental take permits on listed salmon and steelhead; 2) external consultation with the Fish and Wildlife Service analyzing the effects of NMFS issuing section 10(a)(1)(b) incidental take permits on listed bull trout and other species not under NMFS's authority; and/or 3) concurrent section 7 consultation by both NMFS and the Fish and Wildlife Service with FERC analyzing the effects of amending existing licenses to implement the provisions of the proposed HCPs. The latter would be technically feasible if implementation of the HCP coincides with issuance of the required license amendments. Of these three pathways, the Fish and Wildlife Service views concurrent section 7 consultation with FERC as the approach most likely to assure the development of new information and expedite the consultation process. Consideration of all affected species in the planning process (e.g.,

finalization of the HCPs, FEIS, and FERC license applications) would effectively streamline the various potential elements of future consultation processes. The Fish and Wildlife Service will work with NMFS, the PUDs, and FERC to further identify bull trout biological information, potential effects related to hydroelectric project operations, and mechanisms to reduce or eliminate any potential adverse effects for inclusion in the FEIS and HCPs.

SPECIFIC COMMENTS

41 S.5.3.8, page S-22. Tributary Conservation Plan. It is our understanding that the Douglas PUD Tributary Program contribution could be reduced if total project survival is greater than 95 percent, not 95 percent dam passage survival as listed.

42 1.6.3, page 1-15. Alternative 3. Another unresolved matter in the HCP is the status of parties such as an agency or Tribe not signing the HCP. How would FERC deal with their Federal Power Act and other authorities concerning these projects if they remain outside of the agreement?

43 2.6.3.3, p.2-53. Alternative 3. According to this section, each of the signatories to the HCP agreement agrees not to institute any action under ESA, the Federal Power Act, the Fish and Wildlife Coordination Act, or the Pacific Northwest Electric Power Planning Conservation Act. This statement should be altered to state that these restrictions pertain to plan species at these projects only.

44 3.2.8.1, p.3-50. Bull Trout. This section indicates that bull trout are only occasionally observed in adult and juvenile passage facilities of the mid-Columbia River Dams. More recent information provided by Douglas PUD and Chelan PUD indicates yearly observations of adult bull trout seen passing through fish ladders at Wells Dam and Rocky Reach Dam. This information should be included.

45 3.2.9.3, p. 3-63. Steelhead. This section should utilize more recent information generated by radio telemetry studies to describe migration patterns in the mainstem and tributaries. This information is available in the draft report, Assessment of Adult Steelhead Migration through the Mid-Columbia River using Radio-Telemetry Techniques, 1999-2000 by Karl English, Cezary Slinwinski, Bryan Nass and John R. Stevenson.

46 4.2.1.3, p. 4-10. Action Analysis. It is not clear in this discussion how having or not having the Grant PUD projects under the HCP standards or under situations similar to Alternatives 1 and 2 effect the outcome of the QAR analysis and the potential success of HCP measures in meeting recovery for the listed plan species. This needs to be clearly addressed.

47 4.2.1.10, p 4-15. Methow River Steelhead. If the assumptions (p.4-11) concerning low hatchery fish contribution to natural production are not valid, then steelhead would not likely meet recovery criteria under the HCP. Studies to evaluate the success of hatchery fish in natural

production are absolutely critical to determining if the HCP measures for this species would lead to recovery. These studies must be done as part of this HCP to determine the appropriate level of hatchery compensation for long term recovery.

Additional Data Needs

48 The 2001 water year is proving to be an extraordinary year. The Department believes that the FEIS should fully consider emerging scientific information and data that will result from the analysis of the 2001 juvenile outmigration season. The importance of fully utilizing the most recent data cannot be overemphasized, and is particularly significant when tribal trust property is at stake. See Seminole Nation v. United States, 316 U.S. 286, 296-97 (1942) (describes the exacting standards that must be followed by the United States in its trustee capacity). Pursuant to the ESA, an incidental take permit applicant is required to establish that the incidental take will not "appreciably reduce the likelihood of the survival and recovery of" the plan species. 16 U.S.C. § 1539(a)(2)(B)(iv). The results of this year's outmigration may alter some of the basic assumptions underlying the HCPs. Consideration of this year's extraordinary circumstances is consistent with NMFS's obligation to base its decisions on the best available scientific information. This information includes the effects of natural climatic variations such as drought, and the resultant increased juvenile mortality that is acknowledged to be an outcome of the current FCRPS emergency operations plan.

49 The presence and operation of the projects create many difficulties for adult salmon and steelhead that return upstream to spawn. For example, adult telemetry studies indicate that adult fish experience significant delays in the tailraces of the dams and in the trifurcation pool areas of the fishways. *See* Stuehrenberg, et al., *Migrational Characteristics of Adult Spring, Summer and Fall Chinook Salmon Passing Through Reservoirs and Dams of the Mid-Columbia River* (1994). These delays can cause adult fish to deplete their energy reserves and may lead to increased adult mortality. In addition, the process of traveling through the reservoirs and the fishways may cause increased stress to adult fish. Given these kinds of impacts and the uncertainties related to the measurement of delayed adult mortality and total project survival, the Department believes the HCPs should be modified to include specific actions to minimize delay and adult mortality at the dams and fishways. This could increase the likelihood of achieving the 91 percent total project survival standard. Improving passage conditions for adults is consistent with incidental take permit criteria that require applicant's to minimize and mitigate the impacts of incidental take to the maximum extent practicable. This issue should be addressed in the FEIS.

SUMMARY COMMENTS

The Department concurs with the DEIS's findings that certain portions of some of the alternatives considered are or may be inconsistent with the requirements of section 10 of the Endangered Species Act or current science and technology. Clearly, these inconsistencies require clarification and include issues related to HCP performance standards, verification of standards, adjusting and

maintaining hatchery compensation levels, and future consultation with the U.S. Fish and Wildlife Service regarding the effects of permit issuance and HCP implementation on bull trout. In addition, the Department is concerned that the DEIS does not adequately address the effects of the proposed action on Indian reserved rights and resources that are subject to the Federal trust responsibility. We are especially concerned that by implementing HCPs as presently proposed, the NMFS would transfer the Federal government's obligation as trustee for the Tribes fisheries to non-federal, commercial entities. We recommend that NMFS renew its efforts with the PUDs to address these issues and attain the support of the Tribes regarding implementation of the HCPs.

We appreciate the opportunity to comment on this draft environmental impact statement for the Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects, Washington. If you have questions or require clarification regarding any of the fish and wildlife comments contained herein, please contact Mark Miller, Project Leader, U.S. Fish and Wildlife Service, Eastern Washington Ecological Services Office, 32 C Street NW, P.O. Box 848, Ephrata, Washington 98823 (509-754-8580). Questions or clarifications for the Bureau of Indian Affairs should be directed to Stan Speaks, Regional Director, U.S. Bureau of Indian Affairs, Northwest Regional Office, 911 NE 11th Avenue, Portland, Oregon 97232-4169 (503-231-6702). If you have any other questions please contact me at (503) 231-6157.

Sincerely,

Preston A. Sleeger

Bob Dach
National Marine Fisheries Service
525 NE Oregon Street, Suite 420
Portland, OR 87232-2737

Dear Mr. Dach:

We have reviewed the draft Environmental Impact Statement (EIS) for the proposed *Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (CEQ #000464) in accordance with our responsibilities under the National Environmental Policy Act (NEPA) and §309 of the Clean Air Act. The draft EIS evaluates the decision to authorize incidental take permits for 50-year anadromous fish agreements and habitat conservation plans (HCPs) with two Washington State public utility districts (PUDs) to protect five species of Columbia River steelhead and salmon, two of which are currently listed as endangered under the Endangered Species Act.

We have rated the EIS, EO-2 (Environmental Objections- Insufficient Information). We base our environmental objections to the project on the selection of Alternative 3 as the preferred alternative. Our objections are primarily based on the lack of information and the lack of proposed measures that demonstrate that fish species of concern would be protected under the framework provided by the HCPs as described in the EIS. Specific sources of our objections are

- the failure to include listed Columbia River bull trout in the HCP;
- the lack of key biological information in the EIS that is presently slated for later development in the biological opinion;
- the lack of information on water quality impacts, namely total dissolved gas and temperature from the existence and operation of the three PUD dams;
- yet undeveloped or agreed upon methods of measuring compliance with standards established in the HCP; and
- an explicit statement that future interpretations of information will not favor protecting fish over other interests.

This rating and a summary of our comments will be published in the *Federal Register*. A copy of the rating system used in conducting our review is enclosed for your reference. Thank you for the opportunity to review this draft EIS. If you would like to discuss these issues, please contact Chris Gebhardt at (206) 553-0253.

Sincerely,

Judith Leckrone Lee, Manager
Geographic Implementation Unit

EPA Detailed Comments on the EIS
for the Proposed Anadromous Fish Agreements and Habitat Conservation Plans
for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects

General Comments

The Environmental Protection Agency has environmental objections to adopting the preferred alternative (Alternative 3) which uses anadromous fish agreements and habitat conservation plans (HCPs) to address Endangered Species Act (ESA) concerns associated with the Wells, Rocky Reach, and Rock Island dams in the Mid-Columbia Rivers for the next 50 years. The primary reason for our objections is that information and proposed measures do not demonstrate that fish species of concern would be protected under the framework provided by the HCPs as described in the EIS. We are also concerned that the HCP does not include Columbia River bull trout and that the EIS lacks information on water quality impacts, namely that of total dissolved gas and temperature, caused by the operation of the dams.

HCP Framework and EIS Do Not Demonstrate Sufficient Protection of Salmon and Steelhead

Alternative 3 proposes using anadromous fish agreements and HCPs in lieu of adopting the no-action alternative and complying with ESA through Section 7(a)(2). ESA calls for the protection and restoration of listed species, however, the HCP, as it is currently written, does not provide assurances that populations of salmon and steelhead would be protected and restored in the mid-Columbia River for 50 years. The HCP is based on an adaptive management framework which accepts less front-end planning, greater gaps in understanding, and fewer commitments to do specific actions to protect and restore fish. This, in turn, exposes the listed fish species to more risk because the requirements to protect and restore fish, and to measure their status become subject to future interpretation.

The HCP proposal found in the EIS is additionally problematic because

- key biological information on salmon and steelhead is not in the EIS (instead it is slated for inclusion in the Biological Opinion (BiOp));
- another listed species, Columbia River bull trout, are not included in the HCP;
- technology to monitor compliance does not presently exist; and
- the EIS states that issues that arise (and with adaptive management, there are bound to be many) will not necessarily be resolved so that fish protection is favored over other interests.

In short, the EIS presents a HCP framework to protect listed species which we found to contain significant gaps, thus reducing assurances that fish will be protected with HCP implementation.

US EPA

1 Although it contains good information, the EIS is also not arranged in a manner that helps the reader understand the overall risks posed to salmon and steelhead throughout their life stages, the specific risks posed to the fish by the dams, the extent of those risks, ways to monitor those

risks, and ways to mitigate those risks. The EIS should clearly explain and illustrate the risks posed to salmon and steelhead in the mid-Columbia River. This discussion should begin broadly with a discussion of the life cycle of the different fish species, maps showing the range of their migrations, and a comprehensive list of sources of injury and mortality (ocean harvesting, natural predation, etc.). This would provide a context by which the reader could view the level of fish injury and mortality occurring in the mid-Columbia River dam complex.

2 The EIS should then contain photographs and diagrams of each dam facility with annotations showing migratory routes, the number of fish using each route, and sources of fish injury and mortality. Supplemental information should state the number or percentage of juvenile and adult fish that use individual migration routes, and the level of fish injury and mortality at specific locations in each dam, for each dam complex, and the overall injury and mortality rate for juveniles and adults that pass all three dams.

3 To better address the risks posed by the dam complex to salmon and steelhead, the HCP should include monitoring that continually assesses the level of salmon injury and mortality salmon as they are passing through the dams and mitigation measures that reduce those levels. Specifically, the EIS should:

- explicitly identify an available monitoring method that could be used to measure compliance and commit to using that method in the Record of Decision (ROD), and
- propose concrete actions that analyses demonstrates is sufficient to protect fish in lieu of basing success solely on fish protection standards.

4 The EIS should also contain biologic information that is planned to be issued in the BiOp so that the public and decisionmaker can review and comment on this key information. 40 CFR 1502.25(a) states that agencies shall prepare draft EISs concurrently with and integrated with environmental impact analyses required by the Endangered Species Act.

Compensating for Fish Loss

5 The EIS proposes to mitigate 7 percent of the 9 percent of salmon and steelhead losses due to dam existence and operation using hatchery supplementation and the remaining 2 percent by improving habitat in tributary reaches. We strongly believe that favoring habitat improvement over hatchery supplementation is a more sustainable practice that benefits other amenities (such as water quality) in addition to fish. At the same time, we understand that treaties entitle tribes to a harvest level of fish and that the only way of guaranteeing this harvest level in the short term (until habitat improvement activities result in increase numbers of fish) is through hatchery supplementation. The EIS should therefore propose to implement the majority of the habitat improvement projects soon after project adoption to maximize the benefits of habitat improvements as quickly as possible. The EIS should prioritize these reaches proposed for improvement and indicate the order by which those listed in the EIS should be restored. The EIS should predict the when and to what extent habitat improvement would result in additional fish numbers and prescribe a commensurate reduction in hatchery supplementation. Finally, the EIS should state the method used to translate 2 percent compensation into the type and level of habitat improvement.

Water Quality

The draft EIS has a good discussion of water quality in the mid-Columbia River, especially highlighting the effects of warm water and high total dissolved gas concentrations on juvenile and adult salmon. However, the EIS downplays the importance of the three dams on the
6 water temperature regime of the river and its potential effects on salmon. The conclusions on temperature have not been substantiated and we are concerned that the EIS underestimates the effects of the three dams on temperature and current in the reservoirs and therefore, the degree to which the dams "result in the destruction or adverse modification of critical habitat" of the plan species.

The DEIS states that the thermal regime of the mid-Columbia is controlled largely by water released at Grand Coulee and the three subject dams do not significantly affect water temperature because of the short water retention times in the reservoirs of each dam. These
7 statements are unsubstantiated. There is no information on travel time in the river without dams or in the reservoirs with dams. There is no temperature data provided that could be used to verify the statements. The EIS says the travel time through each reservoir is a few days. There are three reservoirs in the study and two more downstream, so a few days in each reservoir adds up.

In addition to increasing temperature or causing shifts in the temperature regime so that warm temperatures last longer into the late summer and fall, dams can reduce the diurnal fluctuation of temperature and dampen the cooling effects of short term weather fluctuations. Currently, temperature at all three dams exceeds 18 C at times. At temperatures over 19 C any decreases in temperature can be beneficial, so diurnal fluctuations and short term weather fluctuations might play a role in salmon migrations through these reaches. Further, by slowing down the river flow, dams can cause out-migrating juvenile salmon to be subjected to warm temperatures longer, cause them to expend more energy to migrate, and subject them to increased
8 predation and disease. We believe that these changes in the reservoirs could represent "destruction or adverse modification of critical habitat" by the dams and should be more thoroughly evaluated in the EIS so that actions to remedy the situation or off-site mitigation can be planned.

The EIS suggests that little can be done to offset elevated temperatures because Grand Coulee is not equipped to release cooler water from deep in the reservoir. There are some possible steps that can be taken both to remedy the effects directly and to provide off site mitigation that should be investigated in the EIS. Water to run Grand Coulee's turbines is from deep in the reservoir and is cool. Grand Coulee is rarely operated at its capacity. During the short critical period in the summer when temperatures are at critical levels, generation could be diverted to Grand Coulee to release as much cool water through its turbines as possible. This was done in 1961 to cool the Hanford Reach and resulted in temperatures up to 9 F cooler in that reach which is quite a distance downstream from the subject reach. This may require spill from the dams downstream of Grand Coulee, and if so, the trade off between cooler temperatures and increased gas would have to be evaluated.

An offsite measure that might mitigate the effects of the dams on critical habitat would be to augment or create cold water refugia primarily in tributaries (where they are already planned).

For example, creating shade at the mouths of some tributaries could augment the temperature benefits naturally obtained from cool water from ground water wells entering those tributaries.

Detailed Comments

9 Abstract. The EIS proposes 50 year anadromous fish agreements and habitat conservation plans. The EIS should explain the basis of the decision to select a 50 year time frame. The EIS should state whether other time frames would work equally well and whether the HCP is protective enough to ensure fish protection for the next 50 years.

10 Abstract and 1-3. The EIS states that the agreements would provide the PUDs with some degree of certainty for the long term operation of these projects. Please define "some degree of certainty" and explain what elements of the agreements and HCP are subject to future negotiations and which are not. Does the flexibility contained in the agreements and HCP compromise the stable operating environment that the PUDs are seeking or the long term protection of the five species of salmon and steelhead?

11 S-1. The EIS states that "fish protection measures of the HCPs are also intended to satisfy the PUD's obligations under the Federal Power Act, Fish and Wildlife Coordination Act, Pacific Northwest Electric Power Planning and Conservation Act, and Title 77 Regulatory Code of Washington (RCW)." The EIS should also state that HCPs also intend to satisfy the Clean Water Act and State of Washington Water Quality Standards by operating dams in a manner that complies with total dissolved gas and temperature criteria which is also consistent with fish protection. The EIS should also state that the fish protection measures of the HCP are consistent with the Innovative Columbia River Basin Strategy (i.e., All-H Paper Strategy).

12 S-2. The EIS states that the purpose of the HCP is to "support a comprehensive strategy for protecting and recovering five Plan species of anadromous salmonids in the Mid-Columbia River, two of which are currently listed as endangered under the Endangered Species Act." The EIS contains a lot of good information on the fish species of concern, however, the EIS should comprehensively discuss the life cycle of the five species and the sources of mortality and injury during their life cycles. This information should be used to determine how to best protect and recover the species. Such a strategy might include increasing restoration and habitat improvement activities in tributaries or limiting the harvest of salmon on the Columbia River or in the oceans. This information could be elaborated on page S-11 after the statement that, "in addition to improved survival through the middle and lower Columbia River projects, and during early life states of the fish, improved environmental/climate conditions are necessary for the listed species to survive and recover."

13 S-6. The EIS states that the mid-Columbia River dams will continue to be operated to control total dissolved gas levels under total river flows up to the 7-day 10-year peak flow event to 120 percent saturation. The EIS should explicitly state that the 120 percent saturation criteria is a special exemption that applies only when dams are spilling water to aid in fish passage and that the criteria at all other times is 110 percent.

14 S-6. At several places in the document, the EIS states that turbines will be operated at peak efficiency ratings, to the extent possible to protect juveniles. We recommend that the EIS define "efficiency" as it is used in the EIS. Does this mean that the turbines will be operated to maximize power production? In addition, the EIS should explain the connection between operating turbines efficiently and protecting juveniles.

15 S-11, Last paragraph. "Drawdown to minimum operating pool....has not been shown to increase juvenile survival.....Therefore it was not evaluated in this EIS." Has drawdown been tried or evaluated through some kind of modeling exercise? It hasn't been shown to increase survival but has it been shown that it doesn't increase survival? Or is the effect of drawdown an unknown?

16 S-16. The EIS states that prior activities are not considered an action subject to additional mitigation beyond license requirements unless they are considered to cause a continuing "take" of a listed species as defined under the Endangered Species Act. The EIS should clarify what is meant by this statement and use examples.

17 S-17, S.5.3.5, bullet 1. Does the 91% project survival include mortality of juveniles in the reservoir?

18 S-17. The HCP proposes to compensate the 9 percent loss of fish species by providing 7 percent compensation through fishery supplementation and 2 percent compensation through tributary habitat improvement programs. We are concerned that the proposed strategy heavily relies on the non-sustainable practice of habitat supplementation which additionally results in genetic erosion of native fish stocks (see page 2-47 of the EIS). The EIS should propose implementing the majority of habitat improvement projects soon after project implementation so that benefits to fish occur as quickly as possible. In addition, we recommend that the EIS predict when and to what extent habitat improvements result in increased fish numbers and propose a commensurate decrease in hatchery supplementation at that time. The EIS should also identify the method used to quantify the level of habitat improvement needed to provide 2 percent compensation.

19 S-18. The EIS states that the PUDs would use "best efforts" to evaluate, improve, maintain, and operate adult and juvenile fish passage systems to the meet the performance standards. We recommend that the EIS define "best efforts" to ensure that there is clear understanding about the PUDs commitments in the context of this HCP and to ensure that they are sufficient to effectively protect fish species.

20 S-18. The EIS describes HCP phases. We are concerned that the HCP relies extensively on an adaptive management strategy without having the benefit of a completed risk assessment which would evaluate the likelihood of meeting HCP performance standards.

21 S-21. The EIS proposes to create a tributary conservation plan which prescribes activities that would decrease bank erosion, sedimentation, channel scouring, and water quality problems. Restoration activities for the HCP should be matched up with water bodies identified as impaired under Section 303(d) of the Clean Water Act, and should be coordinated with TMDL development and implementation.

22 S-22, first paragraph second column. Will a tribal representative be asked to sit on the tributary committee?

23 S-23 and 1-12. The EIS states that bull trout are a threatened species in the Columbia River Basin and that they also occur in the project area, however, the extent of their occurrence and the project-related impacts are unknown. We are very concerned about the HCP's ability to provide sufficient protection to bull trout when there is a lack of knowledge about the presence of bull trout in the project area and the potential impacts of the project. We strongly recommend that NMFS invite the U.S. Fish and Wildlife Service to become a cooperating agency in the development of the EIS to facilitate adding bull trout as a fish species protected under the HCP. Protecting bull trout in the context of the HCP would likely need to begin with designating critical habitat for bull trout in the Columbia River and the development of ESA Section 4(d) recommendations. The EIS should also state whether dolly varden also occur in the project area, and whether protection would be extended to this fish species, because of the inability to tell this fish species and bull trout apart.

24 Table S-23. Under Water Quality, Project Area TDG, Alt 3: The PUD's agree to take measures to maintain Total Dissolved Gas levels at or below legal maximum levels. Is that referring to the 110% standard or the 120% waiver?

25 S-24. The EIS states that the PUDs would, to the maximum extent practicable, minimize and mitigate the impacts of takings. Please define and give examples of the "maximum extent practicable."

26 S-24. The EIS states that available technology is not sufficient to adequately conduct all of the evaluations proposed in the HCPs for each of the Plan species and there is currently no methodology that all parties support for determining the survival of adult fish through the projects. We object to the concept of employing an adaptive management strategy when technology is not available to evaluate whether the PUDs are successfully meeting HCP performance standards. Monitoring and evaluation are the key to ensuring that an adaptive management strategy is meeting performance standards. We recommend that the EIS characterize the importance of evaluation tools that are not currently developed in the context of this EIS. If these tools are sufficiently important, the EIS should propose using alternative methods of evaluation or, at a minimum, should demonstrate that these tools could be developed in a timely manner.

27 S-27. We recommend that the monitoring section include implementation monitoring, which would ensure that mitigation measures are in place and working.

28 S-33. The EIS states that there is no requirement to provide the benefit of the doubt to the species of concern with respect to gaps in the information base and NMFS has no authority to determine what constitutes the best available information to be utilized in support of any decisions. We believe that the framework proposed in the HCP does not provide sufficient protection to fish species of concern primarily due to an adaptive management approach coupled with methods of evaluation which have yet to be approved or developed. We believe that the loose framework of the HCP will require clarification and information in the future and that the

statement above about information precludes NMFS from providing adequate protection to fish species. We therefore, strongly recommend that the framework be tightened and the level of information in the EIS be bolstered to limit information gaps that would require clarification in the future.

29 S-35. We strongly recommend that all analyses planned for inclusion in the biological opinion be included in the EIS. Many of the analyses that we believe necessary to include in the EIS for adequate information disclosure and to ensure protection of fish species are listed as studies to be described in the biological opinion. The purpose and need of this proposed action is to protect and restore Columbia River salmon and steelhead species to comply with ESA and issues related to biological parameters should be discussed in the EIS. This information should have been presented in the draft EIS to be consistent with NEPA which requires that Federal agencies shall "to the fullest extent possible...prepare draft environmental impact statements concurrently and integrated with environmental impact analyses and related surveys and studies requested by Endangered Species Act (40 CFR 1502.25(a))."

30 S-36. Table S-3 states that if reservoir drawdown occurs, erosion and reservoir turbidity would initially increase over the short term and damage aquatic habitat conditions with the greatest damage occurring the first 4 to 7 years. The EIS should identify ways to mitigate these impacts if any exist.

31 S-38. Table S-3 states that although maximizing survival at each of the PUD dams will increase the return rates of spring-run chinook salmon and steelhead, populations will continue to decline without reductions in non-hydro system related impacts, although at a slower rate than Alternative 1. We strongly agree with this statement and therefore strongly recommend that the EIS describe the life cycles of the fish species of concerns and the souces of mortality and injury during different stages. We believe this information is critical to determine how to best protect and restore the species.

32 1-3. We were pleased to read that the purpose of the HCP is to protect fish in the Mid-Columbia River and not to merely satisfy ESA requirements. We, however, recommend that the EIS contain an objective that is less prescriptive than generating electricity, such as helping to provide electricity to meet local electricity needs. This broader purpose and need statement would allow options such as conservation if additional fish protection is needed and would also give priority to power production that served the needs of local people over that for exportation. The EIS should also discuss tensions that exist when operating the dams for power production versus fish protection and existing legal and policy requirements for fish protection and electricity production.

33 1-17. The EIS identifies activities significantly impacting salmon including hydroelectric and irrigation projects; commercial and sport fishing; logging; mining; livestock grazing; water use by farms, cities, and towns; and municipal and industrial pollution. We recommend that the cumulative effects section in the EIS describe in quantitative terms the extent that these activities impacts the fish species of concern. This will better allow the reader and decision-maker to understand how to protect and restore salmon and steelhead in the Mid-Columbia River.

34 1-17 and 2-7. The EIS contains a germane discussion of the power aspects of this project. It states that the Northwest Power Planning Council projects an energy deficit of 25 million megawatts by 2003. We recommend that the EIS state whether this is a net deficit, or in other words, does the Northwest produce 25 million megawatts less than they use or is the deficit partly attributable to exporting electricity. We believe that this is an important point in the context of the scope of the project (the Mid-Columbia River dams) and a statement in the following paragraph that these dams were developed primarily to serve customers in nearby areas and the statement on page 2-7 that the three dams produce 14 billion kilowatt-hours or 6 percent of the hydropower in the U.S.

35 1-18 and 1-32. The EIS identifies two additional Mid-Columbia River PUD dams, Priest Rapids and Wanapum, that are not covered in the scope of this EIS. The EIS should explain why these two facilities were not included as part of the EIS (i.e., why Grant County withdrew from the HCP development process) and should characterize how their absence from the HCP affects fish protection and restoration.

36 1-27. In the section describing EPA's responsibilities, the EIS should identify our Clean Air Act Section 309 responsibility to review the significant federal action described in this EIS.

37 1-31. The EIS correctly states that NMFS must identify critical habitat for listed species. The EIS should also state that U.S. Fish and Wildlife Service must identify critical habitat for Columbia River bull trout.

38 1-31. The EIS states that the biological opinion will determine whether the species can be expected to survive with an adequate potential for recovery under the proposed action. Again, we believe that this is critical information for inclusion in the EIS and that the EIS should state what the predicted potential for recovery is for all alternatives. This would better allow the public and decision-maker to understand this key issue and to allow the decision-maker to make the appropriate decision.

39 1-31. The EIS states that the biological opinion will identify reasonable alternatives to the proposed action if it is likely to jeopardize listed species. Because the biological opinion was not developed concurrent with the development of the draft EIS as required by NEPA (40CFR1500.2(c)), any reasonable alternatives identified would require a supplemental EIS to describe the new alternatives and the environmental consequences of adopting them. We recommend that NMFS develop the biological opinion prior to issuing the final EIS and include information and analyses developed for the biological opinion in the EIS. Finally, NMFS should issue a supplemental or revised EIS to fulfill NEPA requirements for all newly developed alternatives.

40 1-32. The EIS states that the original ecosystem based management approach was abandoned as overly ambitious in favor of HCPs that focus specifically on the five Plan species. The EIS should present this in chapter 2 as an alternative considered but eliminated from detailed evaluation. The EIS should describe in more detail why the ecosystem approach was abandoned? Was it economically or technically infeasible? Were there time restraints?

41 2-2. The EIS states that reasonable and prudent measures or alternatives and the terms and conditions of the biological opinion would remain in effect as long as new information did not indicate that the species' continued existence was in jeopardy. We are concerned that the HCP relies on new information for ensuring the protection of fish species of concern when the EIS indicates that evaluation methods are not universally accepted or are not technically feasible. We are also concerned that this criteria ignores the ESA requirement to restore listed species. We recommend that the appropriate evaluation techniques be developed for the HCP and identified in the EIS and that the above statement be changed to read that reasonable and prudent measures or alternatives and the terms and conditions of the biological opinion would remain in effect as long as new information did not indicate that the species continued existence was in jeopardy or was failing to recover.

42 2-4. The generic dam diagram helps the reader identify components and understand how a dam operates. To improve the document more, however, we recommend that the EIS include a number of diagrams and photos illustrating the existing and proposed layouts for each dams including mitigation measures, monitoring stations, etc. In other words, the EIS should contain diagrams that illustrate the information listed in table 2-3 for each dam.

43 2-8 and other pages. The EIS does a good job identifying locations where fish could become injured or die when passing through the three dams. We recommend that the EIS include diagrams for each mid-Columbia dam that shows passages, the number of fish that use each passage, and injury and mortality rates at each obstacle. We believe that our recommendation is consistent with a statement on page 2-9 that the proportion of fish passing through spillways and bypasses is essential information for estimating the overall survival of juvenile salmon and steelhead passing a project and a statement on page 2-12 that fish bypass systems are fairly complex systems that can include turbine intake screens, gatewell orifices, etc. These features vary by project, and all of them affect the survival rate of juvenile salmon and steelhead.

44 2-18. The EIS states that current natural anadromous salmonid spawning in the mainstem Mid-Columbia River is limited primarily to the Hanford reach and major tributaries. The EIS should contain an estimate of how much spawning area is lost due to the dams and, if necessary, how compensatory spawning areas could be created or enhanced.

45 2-22. The EIS discusses salmon predators and predator control programs. The EIS should estimate injury and mortality rates caused by predators and the effectiveness of predator control programs to reduce predation.

46 3-28. The EIS describes lower population numbers for the species of concern during the 1990s. The EIS should explain recent population declines in the last decades despite increased attention and effort being given to saving salmon and steelhead species.

47 3-37. The EIS identifies information gaps here and on pages 3-58 and 3-67 among others. The EIS should contain a table listing research needs. The table should also include a schedule indicating when studies need to be conducted or an indication of high and low priority projects.

48 3-37 and 3-47. The EIS states that it is not possible to differentiate between natural and

hydrosystem caused mortality at this time. We believe that this is a key question that demands research attention. The EIS should define sources of hydrosystem and natural mortality to better formulate the parameters of the question. For example, are factors attributed to dams, such as increased predation and habitat loss, considered natural or hydrosystem sources of mortality.

49 3-50. The EIS states that the effect of the projects on isolating populations and on the genetic fitness of bull trout is unknown. We recommend that NMFS consult with U.S. Fish and Wildlife Service about the proposed actions and their impacts to bull trout. The consultation process should help fill information gaps about bull trout in the project area and the impacts of the dams and their operation on bull trout. The EIS should contain this information. We believe that the best way to ensure the protection and restoration of Mid-Columbia bull trout is to include them as a species of concern in the HCP.

50 3-52. The EIS states that reservoir releases are typically cooler in the spring and summer and warmer in the fall and winter. The EIS should also state that dams releases have fewer temperature fluctuations with cool moments for salmon and steelhead to take refuge in during hot periods.

51 3-55. The EIS describes sediment deposition. The EIS should state whether sediment deposition behind the Mid-Columbia dams would require dredging, and if so, the frequency of the dredging and the impacts of the dredging to fish species of concern.

3-81. We found the key terms and definitions to be a useful addition for readers who are not familiar with terms associated with water resources.

52 3-87. The EIS states that Washington Department of Ecology is not permitting new water rights to withdraw water from several of the Mid-Columbia River tributaries to address dewatering. The EIS should describe the effectiveness of this mitigation measure and the extent that dewatering still affects fish species of concern.

53 3-89. The statement that the "Entiat River flows between the Entiat River and Chelan mountains" is confusing. Please clarify or rewrite the description.

54 3-95, Last paragraph, first column: "Total dissolved gas supersaturation is the foremost water quality concern in the mid-Columbia River." This statement has not been substantiated. We do not believe that the temperature impacts from these dams and from increasing the length of exposure of juveniles to these temperatures have been adequately evaluated. TDG waivers from water quality standards are granted because it is believed that the risks posed by gas at levels up to 120% are outweighed by the benefits of moving fish downstream. There are no benefits that outweigh the effects of subjecting fish to elevated temperatures with the concurrent hazards of predation for longer periods of time.

55 3-97, fourth paragraph, first column. "The very rapid flushing rates.....Water temperatures do not appear to be significantly warmed through the mid-Columbia projects." Neither the flushing rates nor the temperature statements are substantiated with data or analysis. These statements are very important and should be substantiated.

Portland, OR 87232-2737

Dear Mr. Dach:

WDOE

1 Thank you for the opportunity to comment on the draft environmental impact statement (EIS) for the Habitat Conservation Plan for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects. As the state agency responsible for protecting the waters of Washington State for fish habitat and other uses, we support your ongoing efforts to find improved methods for fish. As you know, one of our responsibilities is to address water quality, and particularly, in this case, temperature.

The draft EIS does not evaluate measures for improving temperatures in the Columbia River. As you know, temperature has a significant impact on fish habitat, rearing and migration. It is possible that changes might be made to improve one or more of the following: the distribution of temperatures within the river, the timing and/or duration of temperatures at critical times and/or critical locations within the river, and the overall temperature of the river. The EIS should evaluate changes to dam operation and/or associated structures that might address this issue.

The main impacts to water temperature by dams in a river the size of the Columbia River are through increased solar radiation, caused by reduced speed of water movement down the river and increased overall surface area. Operation of the dam also has modified timing and patterns of water movement down the river. By ponding waters, dams also impact recharge of cooler groundwater to the river.

The EIS should consider modifications that might counter these negative impacts, especially during critical times. Some options to consider: 1) Reservoir drawdown, which might both increase the speed of water movement through the reservoir and reduce surface area exposed to the sun. 2) Modified patterns of turbine operation. 3) Change in the timing of water releases (by days or even by hours). 4) Increased recharge of cooler waters in areas impacted by fluctuating river levels.

Thank you for your considering our comments. If you have any questions, please contact Ms. Pat Irle with our Water Quality Program at (509) 454-7864.

Sincerely,

Rebecca J. Inman

RE: Draft Environmental Impact Statement for Anadromaous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects

Dear Ms. Fruchter:

The Washington Department of Fish and Wildlife (WDFW) has reviewed the subject document and participated in the development of the proposed Habitat Conservation Plans (HCP) and associated appendices. The WDFW appreciates the efforts of the National Marine Fisheries Service (NMFS) and associated preparers to produce a comprehensive and concisely written Draft Environmental Impact Statement (DEIS).

Through our participation in the lengthy process which developed the proposed draft HCPs, we generally accept that the goals and framework of the proposed HCPs should be sufficient to meet our standard of No Net Impact (NNI) regarding the operational impacts of the Wells, Rocky Reach, and Rock Island hydroelectric projects to the anadromous salmonids of the Mid-Columbia River. However, there are specific issues which either were not resolved at the time the draft HCPs were submitted for environmental review or have been brought to light in the course of scoping meetings conducted during the preparation of the draft EIS for the HCPs.

The WDFW has the greatest concern regarding the following issues, and views the satisfactory resolution of these issues as essential for acceptance of the HCPs. These are issues that are germane to the implementation of the HCPs, and are not an attempt to re-negotiate the draft HCPs.

WDFW

Achievement of Survival Standards

1 Modification of project operations and/or structures to achieve specific juvenile and adult survival standards associated with passage of the projects during migration is the major objective of the proposed actions. The proposed HCPs are specific regarding the standards of 95% survival at the project for juveniles and 91% total project survival for both juveniles and adults, but there is lack of specificity regarding how to measure the achievement of the standards. In part this was intentional in order to allow for accommodation of new technologies as they might become available. However, to the extent that survival evaluation of specific species or life stages is not practicable in the time frames required under the proposed HCPs a specific methodology needs to be established for using surrogate data to estimate achievement of survival standards. This methodology needs to be developed by the parties to the proposed HCPs and incorporated prior to finalization of the proposed HCPs. Clarification is also necessary to specify that survival standard confirmation is required for each migrant life stage of each plan species. This confirmation must be provided through either direct evaluation or estimates based upon methods and data agreed to by the parties. In addition, the survival standards must be presumed to **not be met** until the specific confirmation as discussed above has been documented and certified by the coordination committee.

Hatchery Compensation Plan

2 Since the implementation of juvenile survival improvement measures at the dams is essentially capped at 95% juvenile passage survival, it is imperative that the 7% hatchery based compensation be provided to achieve the overarching goal of No Net Impact for each plan species. WDFW recognizes that there may be situations in specific years where abundance of broodstock and/or logistical constraints associated with broodstock collection preclude the full execution of programs for which the PUD's have provided the facilities and other resources to meet the production goals. However, discussions with NMFS during the coarse of this NEPA review process have made it clear that NMFS may limit hatchery based production to something less than the 7% levels specified in the Mid-Columbia River Hatchery Program, to avoid conflicts with the recovery of listed species. If such production limitations do occur and are of substantial duration, we need to provide a mechanism for an alternate form of meeting the hatchery based compensation obligation.

Dispute Resolution Process

3 Our concern regarding the dispute resolution process relates to the issue of the burden of proof when disputes are brought forward through the Alternative Dispute Resolution Process. We are concerned that there may be the opportunity to assert achievement of the survival goals

based upon inadequate scientific assessment. If other parties chose to dispute the assertion they would appear to have the burden of trying to provide proof without an adequate information having been developed to support the initial assertion. As discussed above, WDFW believes that survival goals should be assumed to **not be met** until confirmation is achieved via the coordination committee. This status would encourage all parties to work cooperatively to develop appropriate data and data gathering techniques to assure that the HCP measures are meeting the survival goals.

Adult Survival

4 Adult survival associated with passage at the dams is clearly included in the total project survival goal of 91%. However, there is no specific language requiring or specifying a mechanism for assessment of adult passage survival. Adult passage survival must be assessed either directly or indirectly to provide adequate assurance that the 91% total project survival goal is being achieved for each plan species. Assessment of adult passage survival should be added as an additional function of the Coordinating Committee.

System Survival

5 The Quantitative Analytical Report (QAR) as discussed on page 2-28 indicates that passage survival improvement is required at **all** Mid-Columbia projects as well as Lower Columbia federal projects to achieve an acceptable probability of achieving recovery for the listed populations. The lack of participation by Grant County Public Utility District (PUD) in the HCPs has been a concern to WDFW. We are currently working through the relicensing process for Grant County PUD's Priest Rapids Project to assure survival improvement comparable to the survival goals of the HCPs. We are also working with NMFS through the regional forums established in the 2000 Biological Opinion for operation of The Federal Columbia River Power System to achieve increased survival for plan species at McNary, John Day, The Dalles, and Bonneville Dams. If the survival improvements for these other portions of the system are not achieved, the adequacy of the survival goals of the HCPs may need to be reassessed.

Alternative Selection

6 Due to the substantial unresolved issues discussed above regarding the proposed HCPs and the extreme difficulty for successful implementation which these issues pose, the WDFW recommends that additional consultation and negotiation occur between the potential HCP

parties prior to NMFS selection of Alternative 3 for implementation.. If additional consultation and negotiation do not result in satisfactory resolution of these issues in a timely manner, WDFW will endorse Alternative 2.

Sincerely,

Jeff P. Koenings, Ph.D.

The Washington Growers Clearing House is a non-profit tree fruit grower association representing approximately 2,600 tree fruit growers in North Central Washington.

I am writing on behalf of our membership to express our strong support for the Mid-Columbia Habitat Conservation Plan.

This particular plan maximizes the opportunity to create a meaningful salmon and steelhead recovery and protection program while creating the certainty that is necessary to enable the region to remain economically viable.

The economic engine that drives the economy in North Central Washington is the Washington Tree Fruit Industry. The Tree Fruit Industry has been able to offset most of the advantages of our competition because of three factors: 1.) The excellent climate, 2.) Development of an efficient cost effective water delivery system, and 3.) Low electric rates. The low electric rates have enabled individuals to justify the expenditure of billions of dollars on industry and community infrastructure. A reliable supply of low-cost electricity is the key component in ensuring the future economic survival of the Washington Tree Fruit Industry and the economy of North Central Washington.

Far too much time, money and effort has been spent on a wide range of scientific based salmon recovery efforts with very little measurable results. This particular Habitat Conservation Plan takes a unique new approach, one that is based not only on local input from all stakeholders, but on measurable results. This Habitat Conservation Plan recognizes that one size does not fit all, and that to be effective a program must be flexible, comprehensive and results oriented. This plan gives the local Public Utility District the flexibility necessary to produce a successful outcome. As situations change it is important that the recovery plan has the flexibility and opportunity to change in an innovative and timely manner.

Another crucial component of this HCP is the creation of an invaluable source of funding to aid local citizen group efforts to protect and improve fish habitat on Columbia River tributaries.

The Habitat Conservation Plan ensures that fish and people can live together and that vital hydroelectric production can continue. The Chelan County Public Utility District has responded to the citizen's demands that they be a good steward of this valley's resources. The Habitat Conservation Plan is another example of the PUD's commitment to the citizens, the environment and the resulting quality of life so highly valued by the citizens of North Central Washington.

Sincerely,

Kirk B. Mayer, Manager

Mr. Bob Dach
Hydro Division
National Marine Fisheries Service
525 NE Oregon St.
Portland, OR 97232-2737

Dear Mr. Dach:

We applaud NMFS, Chelan and Douglas PUDs for their efforts to develop long-term habitat conservation plans for the Wells, Rocky Reach and Rock Island Hydroelectric Projects. These plans are an important component in the state of Washington's continuing effort to recover listed anadromous salmonids.

The proposed Anadromous Fish Agreement and Habitat Conservation Plans are particularly timely given the Northwest's present short supply of renewable electric energy. Our region is presently struggling to maintain its economic viability, given recent developments in the wholesale power market. Solutions to these issues must be found through proactive planning and long-term solutions. The proposed HCP represents both of these ideals.

We support the proposed Wells, Rocky Reach and Rock Island HCPs as the preferred alternatives for salmon recovery in the Upper Columbia River. The selection of the long-term HCPs over the alternative of narrowly focused Section 7 consultations will ensure the future viability of anadromous salmonids while maintaining the benefits of clean, renewable hydroelectric power generation. We encourage the fisheries service to select and fully implement Alternative 3 as described in the Draft Environment Impact Statement for the proposed Wells, Rocky Reach and Rock Island Anadromous Fish Agreements and Habitat Conservation Plans.

Sincerely,

Steve Johnson
Executive Director

Portland, OR 97232-2737

As members of the Wenatchee Reclamation District Board of Directors we are writing to support the Mid-Columbia Habitat Conservation Plan (HCP).

How the precious water resources of this valley are used to benefit people and fish is a major concern for us.

The hydropower produced at Chelan County PUD's dams is vital to the economy of the region. It is affordable, reliable and renewable. The Habitat Conservation Plan ensures that hydropower generation can continue while listed salmon and steelhead stocks are protected.

The parties to the HCP should be applauded for working cooperatively. All too often, the command-and-control approach has led to endless, costly court battles. When that happens, nobody wins.

Specifically, we note that the plan addresses unavoidable losses. The Chelan County PUD will provide both supplementation hatchery production and funding to improve habitat to achieve the "no-net-impact" standard. The fund will likely provide badly needed habitat improvements on the Wenatchee River, as overseen by a committee process. In addition, the habitat fund could provide money for partnership projects with communities and individuals throughout the river system. We wholeheartedly support this concept.

Thank you for the opportunity to comment in support of the Mid-Columbia Habitat Conservation Plan.

Sincerely,

WENATCHEE RECLAMATION DISTRICT

Dear Sir or Madam:

On behalf of the 1200 physicians and employees of the Wenatchee Valley Clinic, we are writing to endorse the Habitat Conservation Plan of Chelan County PUD.

The Wenatchee Valley Clinic is a growing enterprise headquartered in Chelan County. We are a regional organization with eight clinic locations that offers a comprehensive array of medical and diagnostic services. We serve a geographic area that spans approximately 12,000 square miles; and care for over 125,000 unique individuals annually.

The Chelan County PUD is also a longstanding regional resource. They are a "Good Neighbor" to our region, and have an excellent power generation and delivery system. They are a linchpin in our region's infrastructure, and have been a strong advocate, and responsible steward, of our area's natural resources.

Medicine and energy are both industries operating under intense regulatory requirements and scrutiny. We see these parallels between our business and that of the PUD:

- The PUD is seeking cost-effective means, compatible with its other business needs, to meet regulatory requirements for resource protection
- The PUD knows the region and its business better than others from outside the region, and should be given the opportunity to apply that knowledge toward finding optimal solutions to salmon recovery issues
- The PUD (and the region) need assurances, provided in the Habitat Conservation Plan, that it can continue the business of maintaining an economical and reliable energy supply while working diligently to develop and institute mitigation and enhancement plans.

Chelan County PUD is regarded as an outstanding citizen, and as an integral component, of North Central Washington. The PUD has a long history of providing both a reliable energy supply and protecting our environmental resources. We urge you to continue toward quick adoption of the Habitat Conservation Plan.

Sincerely yours,

James W. Brown

Gentlemen:

For the past 30 years I have been familiar with the Chelan County PUD stewardship of their three hydro electric projects here in central Washington. I am an avid recreationalist and very active in community development projects. One of those projects was the completion of our Columbia River Loop Trail. Citizens, through an organization known as Complete the Loop Coalition, raised money through private donations and grants to build a six-mile trail on the east shore of the Columbia River so it could be linked to the trails which were built by the Chelan County PUD in connection with the Exhibit R project in the late 1980s. The completed 11-mile loop trail, in my humble opinion, is the diamond in the crown of the many wonderful recreational opportunities created by the PUD here in central Washington.

It was because of the vision of Kirby Billingsly, a former commissioner and manager of Chelan County PUD, that a series of parks line the shore of the Columbia River where hydroelectric reservoirs have been created by the PUD's dams. The financial backing of the PUD and these hydro electric projects made that vision a reality. The PUD's subsequent stewardship through the operation of the parks that have been built has been complimented by museums, fish hatcheries, and educational programs that it has supported. Without question, the PUD has proven to be an excellent steward of the community's resources.

I am currently serving as the president of Wenatchee Valley College. The college looks forward to a close working relationship with the PUD for future educational programs. Some of our students are working on salmon habitat recovery efforts on the Icicle River. Much needs to be done on habitat recovery, and it is frustrating to hear the PUD respond that they cannot spend resources on securing habitat at the present time because the Habitat Conservation Plan (HCP) has not yet been finally approved. There was much fanfare in June of 1998 about the HCP and the recovery efforts, but precious little has been done in the intervening time to initiate the habitat recovery efforts because of the slow, laborious review process for the HCP. It seems to me that a rapid and positive approval of the HCP is exactly what is needed for salmon recovery. Quick action would clear up the confusing and conflicting views and agendas of the many stakeholders in the

salmon recovery process. We need natural habitat restored and protected as rapidly as possible if we, as a nation, are really serious about saving these threatened and endangered species. Acquisition of shoreline and conservation easements is in order.

The public is extremely frustrated with the consequences of legal gridlock, and the provisions of the HCP for dispute resolution and cooperative accountability are refreshing alternate solutions to the agonizing and counterproductive lawsuits that clog our system. I am pleased to see that HCP allows for midcourse corrections.

Please consider this an endorsement of the HCP approach and an urgent request for speedy implementation of the HCP. I believe that if the PUD had the confidence that the HCP will be favorably considered by NMFS and the FERC, as well as all the other signatories, they could speed up the process of securing salmon recovery habitat by purchasing options for select parcels of property that are currently for sale in the Wenatchee River and Entiat River tributaries. Please give this serious consideration as it is plain, from preliminary numbers being offered in Washington State legislature, that there will be a tight budget and a probable restriction of other funds available for securing habitat through the Washington Wildlife and Recreation Program.

There is one other unrelated matter that I wish to bring to your attention. As a citizen volunteer, I have been working for five years to get an extension built along the shoreline for the Columbia River Loop Trail referred to in the first paragraph of this letter. This trail extension is proposed to be operated by Washington State Parks and connects the Confluence State Park (built with PUD Exhibit R money) to Lincoln Rock State Park (also built with PUD Exhibit R money). This extension is approximately 4.5 miles long. I am told that all agencies have reviewed and approved the biological assessment prepared by Washington State Parks except for National Marine Fisheries Service. It seems to me to be fundamentally sound logic that a riverfront trail adjacent to the river would be far preferable for salmon habitat than the potential for sprays and fertilizer residue finding its way to the river from adjoining agricultural lands. The biological assessment for this trail has been in NMFS hands for several months. I cannot understand why NMFS has taken so long to review this project and would certainly hope that it would have a positive response when its review is complete.

Very truly yours

Robert L. Parlette

To whom it may concern:

I am writing to offer my hearty support for the Habitat Conservation Plan for salmon. The plan, developed by Chelan and Douglas public utility districts, is the result of government agencies, tribes and environmental groups working together. It is proof that organizations with opposing views can collaborate to produce a compromise that is beneficial to the environment and that also protects a critical source of renewable energy.

I urge the National Marine Fisheries Service to approve the HCP. This collaborative effort will result in improved fish runs while preserving an important economic resource for the region.

Sincerely,

Wilfred R. Woods
Chairman of the Board

To whom it may concern:

I would like to offer my enthusiastic support for the Habitat Conservation Plan for salmon that has been developed by Chelan and Douglas public utility districts working in collaboration with various government agencies, tribes and environmental groups.

The plan is a model for demonstrating how organizations with opposing viewpoints can come together and develop a compromise that benefits the environment and protects an important source of renewable energy. The HCP is a landmark agreement that also demonstrates conclusively that these decisions can be made without lengthy, costly legal battles.

I would urge the National Marine Fisheries Service to approve the HCP as a step in encouraging collaborative efforts to balance the need for improving fish runs and at the same time preserving an important economic resource for the region.

Sincerely,

Rufus Woods

Re: Comments of the Yakama Nation on the Draft Environmental Impact Statement for the "Mid-Columbia Habitat Conservation Plans."

Dear Mr ~~Dach~~ Bob:

The Yakama Nation (hereinafter "YN" or "Tribe") hereby submits its comments on the Draft Environmental Impact Statement (DEIS) prepared by the National Marine Fisheries Service (NMFS) on the Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach and Rock Island Hydroelectric Projects (hereinafter "Mid-Columbia HCPs" or "HCPs"). We appreciate the opportunity to provide you with comments pursuant to the National Environmental Policy Act (NEPA), 42 U.S.C. § 4322(2)(c).

The NMFS' analysis under this DEIS and the resulting Final Environmental Impact Statement, and its decisions regarding the HCPs, directly affect the Tribe and the Tribe's treaty-reserved rights. The geographic scope of the HCPs falls within the ceded territory of the YN and the operation of the hydroelectric projects at issue in the HCPs affects the treaty fish on which the Tribe relies. In the Treaty with the Yakima Tribe, 12 Stat. 951, Art. 3 (June 9, 1855), the YN reserved the right of "taking fish at all usual and accustomed places in common with citizens of the United States." Retaining the right to continue its traditional fishing practices was a primary objective of the Tribe during treaty negotiations. Tulee v. Washington, 315 U.S. 681, 684-85 (1942); Washington v. Washington State Commercial Passenger Fishing Vessel, 443 U.S. 658, 664-69 (1973).

The treaty guarantees to the Tribe an equitable share of the fish. See United States v. Oregon, 302 F. Supp. 899 (D. Or. 1969) and United States v. Washington, 384 F. Supp. 312 (W.D. Wash. 1974). Anadromous fish and lamprey have significant cultural and religious significance to tribal members, provide members with subsistence for health and well-being, and contribute to a critical share of tribal commerce in an area of limited economic opportunity. Additionally, the YN actively co-manages the fishery resource along with federal and state authorities and is a party to the Mid-Columbia Proceeding before the Federal Energy Regulatory Commission involving the Chelan and Douglas County Public Utility Districts.

As described more fully below, the YN also participated in the negotiations of the HCPs at issue in the DEIS and thus is intimately familiar with the HCPs and issues of importance to the Tribe. The YN believes that the DEIS misrepresents the YN's participation and fails to identify for the public at large the status of the HCPs as being incomplete, the YN's lack of support for the HCPs at this time, and the real reasons for such a lack of support. We discuss this in further detail below.

Below the YN first sets forth its general comments about the DEIS and then provides specific comments related to specific sections of the DEIS. Please note that these are not necessarily set forth in the order of importance to the Tribe and thus all of the Tribe's comments should receive adequate and equal consideration.

GENERAL COMMENTS

YN

The HCPs Are Unfinished, Incomplete, and Thus Not Yet Ready for Environmental Review

1 As the DEIS recognizes, the negotiation of the HCPs was the subject of much debate and controversy. The DEIS is unclear in its explanation of the negotiation process, as it does not adequately discuss either the scope of, or ground rules for, the negotiation. However, these issues surrounding the negotiation process are important to understanding that the HCPs are incomplete and unfinished at this time.

2 The scope of the negotiations was much broader than that which normally occurs within a usual HCP process because the Public Utility Districts, together with NMFS and the United States Fish and Wildlife Service (USFWS), agreed to negotiate not only an HCP, but also a long-term licensing agreement for the Districts' hydroelectric projects under the Federal Energy Regulatory Commission. The ultimate agreement intended to come out of the negotiation was to be not only an HCP providing long-term ESA protection, but also an agreement that would provide the Public Utility Districts an opportunity to renew their hydroelectric dam licenses without opposition from the parties to the negotiation. Those agreements regarding the licenses were no less important to Public Utility Districts than the HCPs.

As a result of this aspect of the negotiation process, the NMFS, USFWS and the Public Utility Districts invited the YN and other non-agency parties to participate. As this was a long-term and potentially contentious negotiation, the Public Utility Districts hired a professional mediator/facilitator to work with the parties. There was one hard and fast rule of the negotiation to which the parties were expected to adhere: the concept of "Conditional Closure." Under

Conditional Closure, the negotiation was to proceed in such a way as to allow the parties to reach agreement on an issue-by-issue basis with the understanding that such issues were only "conditionally closed," such that there would be no binding effect or agreement on any single issue until everyone agreed on the total package. Conceptually, this general rule allowed a party to agree "conditionally" on one issue that it did not completely accept, but the acceptance would be conditioned on receiving a later agreement on other important issues. If the later agreement could not be made, then there was no agreement on any issue.

3 No one involved in the negotiation was mistaken as to the basis upon which it was being conducted. The Conditional Closure ground rule was echoed time and time again by the Director of NMFS and other NMFS staff, the USFWS representative and the facilitators/mediators. Throughout the course of the negotiations, many contentious points were "conditionally closed" only because the parties expected to come to agreement on other issues as well. All parties clearly understood that if one part of the agreement failed, the entire agreement would fail.

The Tribe entered into the negotiation only because of those assurances, and has scrupulously honored its part of the bargain. Until the negotiations simply stopped, with the Public Utility Districts receiving all of their consideration and YN and other non-agency parties receiving virtually none of the theirs, the Tribe relied on the assurances of the federal government and the Public Utility Districts that they would honor their part of the bargain as well. As we discuss further below, the YN has not agreed to the terms of the HCPs because the terms the YN requires to reach such an agreement have been rejected by the other parties. Accordingly, the negotiation—conducted under the Conditional Closure rule—is unfinished and incomplete. As such, the YN cannot support the HCPs as they are drafted.

It is both disheartening and somewhat shocking that the YN must file comments on the DEIS for the "completed" HCPs in light of the clear fact that there is no agreement on the terms of the HCPs and hence no document upon which the DEIS may be based. The YN participated in the HCP process only on assurances from its trustee, the United States, acting through NMFS and USFWS, that there "would be no deal unless everyone agreed to all aspects of the deal." The Tribe expected the United States to fulfill its best and highest fiduciary responsibility to it in making such promises. Unfortunately and shamefully, NMFS and USFWS have turned their backs on the Tribe in favor of the Public Utility Districts, to whom they owe absolutely no obligation.

There is no disagreement among the parties to the HCP negotiation that the YN has not received the benefits for which it bargained. Nevertheless, the representatives of United States and the parties who have received the benefit of their bargain at the expense of the Tribe, have decided in the interests of expediency to push forward regardless. This results in the DEIS being manipulated in the interests of making it appear that there is an agreement despite the fact that no such agreement exists. For instance, at the second scoping meeting on DEIS, held that the West Coast Sea-Tac hotel, a YN representative asked the NMFS representative why NMFS was going forward with environmental review of a non-existent HCP, particularly because NMFS and everyone else involved in the negotiation knew there was no agreement among the parties. The NMFS representative responded that the environmental review will never "see the light of day unless there is agreement" among all the parties. Currently, there is simply no agreement among

the parties, yet the DEIS is in place and the NMFS appears ready to move forward with choosing a preferred alternative.

An additional and related problem is that the DEIS implies that the HCPs are at least nominally in place and that the Public Utility Districts are currently operating under the HCPs. See, e.g., DEIS at 2-35, 2-41. However, there is no final agency action under which the Public Utility Districts can be allowed to operate. The DEIS is thus tremendously misleading in light of the fact that there are no agreed to HCPs in place and no awarded Section 10 permits. As a result, the Public Utility Districts are currently taking listed salmon without valid ESA protection in violation of Section 9 of the ESA. Instead of pretending that some sort of agreement exists, the NMFS and Public Utility Districts must face the circumstances as they truly exist and proceed to either finalize a valid HCP agreement or move forward with Section 7 consultations to cover the take of listed species. 4

Based solely on the circumstances surrounding the negotiations, the lack of closure on any agreement to the HCPs, and NMFS' promise that this document would not "see the light of day" without such agreement, the NMFS should immediately withdraw the DEIS and seek other means for supplying ESA coverage for current PUD operation. Additionally, notwithstanding the fact that there is no agreement, the comments that follow provide further reflection that the provisions of the HCPs are seriously broken and badly in need of repair prior to any finalization of such a concept. NMFS should withdraw the DEIS on that basis as well. 5

The DEIS Inaccurately Portrays the Tribe's Position

The DEIS portrays the YN's concern with the HCPs as being based solely on the lack of guarantee for hatchery production. As discussed below, the YN believes that the refusal to guarantee hatchery production has the potential to further depress runs in the mid-Columbia, which provides treaty fishermen with virtually no benefit from the HCPs while allowing the Public Utility Districts virtually unfettered generation at their dams. While hatchery production is an issue of extreme importance to the scientific validity of the entire agreement, particularly because the underlying principle of the HCPs' No Net Impact standard is impossible to achieve without a guaranteed and successful hatchery component, this is not the sole tribal issue to be ignored by the HCP parties and the DEIS drafters. 6 7

During the HCP negotiations, the Tribe also requested, in return for its agreement to the other provisions of the HCPs, that it would receive its own "no surprises" type assurance. Such a provision was intended to assure that if the HCPs fail to provide adequate protection and recovery of the fish, then tribal harvest or other tribal interests consistent with the YN's treaty rights would not be the first in line to bear the brunt of NMFS' and USFWS' responsibility to make up the difference. See discussion of No Surprises further below. The YN's proposal for such an assurance has been rejected by NMFS on numerous occasions, yet is nowhere mentioned in the DEIS. 8

Of equal importance is a tribal proposal that the HCPs would not be used by NMFS as a defense in any non-HCP related litigation between it and the Tribe. This is an issue of major importance to the YN, as the Tribe is concerned that NMFS will contend in future litigation that 9

the HCPs satisfy NMFS' treaty obligations to YN and that the YN is estopped from asserting otherwise. The Tribe's proposed language was only intended to make clear that any future litigation "playing field" between it and NMFS would remain level. NMFS rejected this proposal but fails to discuss it in the DEIS.

The DEIS ignores the fact that the rejection of these important issues to the YN results in there being no agreement on any of the provisions of the HCP. The YN's inability to obtain agreement on its proposals results in the Tribe withdrawing its agreement to other "conditionally closed" issues. The DEIS ignores the fact that all parties to the negotiation, including NMFS, agreed that this would be the basis on which the HCP was negotiated. The DEIS needs a fair and frank discussion of the rules and terms of the negotiation so that a reader may judge as to whether or not there is in fact any basis for claiming agreement at this juncture.

10

The DEIS treats the Yakama issues as somehow disjointed from the "overall agreement," implying that the other HCP parties may proceed with their part of the agreement while the YN receives nothing in return. Such a proposal has no basis in law, equity or simple justice for a party that negotiated in good faith for nearly three years but now receives nothing. Again, such an interpretation is both highly misleading and violates the understanding between the parties.

11

Despite the total lack of agreement, the DEIS contains several statements that misrepresent that there is tribal consent to certain terms of the HCPs. For example, the DEIS states that the No Net Impact concept was developed "with tribal biologists," DEIS at page 2-35, implying that there is tribal agreement on that concept. Of major importance is the fact that the No Net Impact concept requires that there be the guaranteed 7% hatchery production component. However, the No Net Impact concept has been effectively destroyed by NMFS' position on hatchery production. Accordingly, to imply that tribal scientists still agree with that vastly altered concept is improper.

12

Finally, the DEIS is devoid of any mention of the YN's efforts to resolve these issues. The DEIS should include information regarding tribal efforts to resolve outstanding issues, including numerous meetings with regional NMFS staff and, on at least three occasions, with high-level policy makers for NMFS and the Department of the Interior in Washington D.C. All of these meetings concluded without success. The DEIS should likewise note that the YN and the Confederated Tribes of the Umatilla Indian Reservation formally provided a written request that NMFS remove their names from the DEIS as parties to the HCP, and even that effort was unsuccessful.

13

14

The Proposed Action—Alternative 3—Fails to Fulfill Federal Trust Responsibilities

The NMFS and the USFWS, as federal agencies, have a fiduciary trust obligation to Indian tribes, which must be carried out according to a strict fiduciary standard. See United States v. Mason, 412 U.S. 391 (1973); Seminole Nation v. United States, 316 U.S. 286 (1942); Felix Cohen, HANDBOOK OF FEDERAL INDIAN LAW 225 (1982). These trust obligations apply to federal agency actions that affect trust resources. See, e.g., Covello Indian Community v. FERC, 895 F.2d 581, 586 (9th Cir. 1990). The agencies thus have a required duty to protect, maintain and enhance the YN's treaty fishing rights and the fish on which the Tribe rely.

The proposed alternative in the DEIS regarding the HCPs fails to meet this strict fiduciary duty for a number of reasons. For example, the HCPs lack certainty for the 7% hatchery compensation levels, which the Tribe believes is a necessary component for rebuilding
15 the Tribe's treaty fish resources. The YN bargained for such hatchery compensation in the negotiations and is unwilling to support the HCPs absent assurances of what the Tribe believes is critical for sustainable populations to fulfill the Tribe's treaty rights to fish. For further details of the Tribe's concerns about this issue, please see our discussion below.

Other examples where the agencies would fail to uphold their trust responsibility under
16 the proposed alternative include the No Surprises assurance (please see our specific discussion of this issue in greater detail below); the agencies' unwillingness to include provisions assuring the Tribe that nothing within the HCPs will be used against the Tribe in future litigation matters; and a general failure to guarantee the protection and enhancement of the Tribe's trust resources. Additionally, the proposed alternative requires that the agencies shift management authority to
17 the Public Utility District within the first five (5) years and also may prevent agencies from taking necessary recovery and rebuilding measures in the event that the fishery resource continues to dwindle despite the HCPs.

Alternative 3 thus frustrates the NMFS's and USFWS' ability to uphold its strict fiduciary duty to the Tribe, yet these factors are not addressed or weighed within the DEIS. The NMFS
18 must adequately discuss its trust responsibility and explain, in a comparison between the alternatives, the extent to which NMFS and the USFWS are able to completely fulfill their roles as trustees to the Tribe and the Tribe's treaty-reserved resources.

NMFS and USFWS Must Comply with the Secretarial Order

A related concern is that the NMFS and USFWS have to date failed to comply with the 1997 Secretarial Order of the Secretaries of Commerce and Interior titled "American Indian
19 Tribal Rights, Federal-Tribal Trust Responsibilities, and the Endangered Species Act." The Secretarial Order requires the agencies to carry out the Endangered Species Act (ESA) in such a way that harmonizes the Tribe's sovereignty and rights with the Secretaries' duties under the ESA. Section 1. The Secretarial Order also requires that the agencies ensure that the Tribe not bear a disproportionate share of the conservation burden for listed species. Section 5, Principle 3.

The DEIS must take the requirements of the Secretarial Order into account. The Tribe
20 finds that the DEIS is deficient of a detailed discussion about how the HCPs and the other alternatives may now, and in the future, be consistent or inconsistent with the Tribe's treaty rights and tribal sovereignty. The DEIS likewise lacks a discussion of whether or not any of the particular alternatives may cause NMFS or USFWS to fail to fully uphold its trust responsibility. Furthermore, under the Secretarial Order, the Tribe has repeatedly asked for a consultation meeting that has not yet taken place. The YN therefore respectfully requests that the NMFS
21 immediately arrange a formal consultation meeting that can take place with the YN's governmental officials and legal counsel on a government-to-government basis. To be

meaningful, such an action must take place *before* the NMFS makes a decision about which alternative to choose as the preferred alternative.

The DEIS Neglects to Address Several Important Legal Issues

Discussion and analysis contained within the DEIS are inadequate or completely lacking on several legal matters that the YN believes deserve due attention. For example, the analysis in the DEIS is cast in terms of ESA recovery, but the nature of what Alternative 3 is meant to
22 legally satisfy is such that the analysis must go beyond mere ESA standards. As the DEIS recognizes, the HCPs would constitute long-term settlements under the Federal Power Act, the Fish and Wildlife Conservation Act, the Northwest Power Planning and Coordination Act, and Title 77 of the Revised Code of Washington. DEIS at S-15. However, the DEIS couches its review in ESA terms without analyzing whether the alternatives meet the requirement of these laws or other laws, such as the United States-Canada Pacific Salmon Treaty and tribal treaty rights.

As one example, the Public Utility Districts plan for the terms of the HCPs to be wrapped into at least one relicensing process for each of the three hydroelectric projects at issue, though this intent is based on an agreement of the parties to the HCPs that now does not exist. The
23 DEIS contains no discussion or analysis of whether the HCPs would independently satisfy the Federal Power Act (FPA) requirements for equal consideration, protection, mitigation and enhancement, which are all standards that would be need to be addressed at relicensing pursuant to the FPA. See 16 U.S.C. §§ 803(a), 803(j). Additionally, because each of the projects would be relicensed during the term of the HCPs if put into place, and thus would presumably be
24 incorporated into their license terms and conditions, the Public Utility Districts may believe that they will receive 50+ years of protection under the HCPs and similarly long-term licenses. The DEIS must address this with the understanding that the YN would likely insist on a traditional relicensing process and assert that the HCPs fail to satisfy FPA requirements.

The proposed HCPs also affect tribal trust resources over a long period of time, so the
25 analysis of impacts on species must also include compliance with treaty reserved rights – including rebuilding to sustainable, harvestable populations over and above what would be required for de-listing under the ESA. As NMFS' own salmon recovery policy provides, "It is our policy that the recovery of salmonid populations must achieve two goals: (1) Restore salmonid populations to the point where they no longer require the protection of the ESA, and
26 (2) restore salmonid populations to a level that allows meaningful exercise of tribal fishing rights. McElhany, P., M.H. Ruckelshaus, M.J. Ford, T.C. Wainwright, and E.P. Bjorkstedt. 2000. Viable salmonid populations and the recovery of evolutionarily significant units. U.S. Dept. Commer., NOAA Tech. Memo. NMFS-NWFSC-42,156 p. 34 (hereinafter "NMFS VSP"), citing (Garcia 1998). The DEIS therefore must provide analysis of the alternatives under the laws referenced above and examine recovery and rebuilding consistent with the NMFS policy.

The Public Utility Districts also plan for the HCPs to constitute a settlement of the Mid-Columbia Proceeding, which is under the continuing jurisdiction of an administrative law judge of the Federal Energy Regulatory Commission, so the DEIS should take into consideration the opportunities, function and protection provided under the Proceeding and all settlements that

have been entered into (the Wells Settlement Agreement, the Rock Island Settlement Agreement, and the past stipulations for Rocky Reach). The existing status of interaction among the parties under the Mid-Columbia Proceeding make up part of the current situation, yet are not thoroughly addressed in the DEIS under the No Action alternative, nor under the other alternatives.

27

The DEIS also neglects to provide sufficient consideration of Clean Water Act requirements for water quality and quantity. Though the DEIS recognizes that the hydroelectric projects at issue have negative impacts on water quality, mainly increased total dissolved gas levels, the DEIS contains minimal discussion of mitigation for such impacts. The only proposed solution that the Public Utility Districts offer is reduced spill. See DEIS at 2-46. The Tribe finds this to be an inadequate solution because spill is one of the most effective methods of safely passing juvenile fish through the projects. Other solutions should be fully explored and addressed across all of the alternatives. The DEIS also recognizes that the projects are exceeding Clean Water Act temperatures, see DEIS at 3-96—3-100, yet the DEIS contains little information about how this problem could be addressed under the alternatives. The DEIS must therefore address Clean Water Act requirements and how such requirements – for both quality and quantity – may be met under the parameters of the HCPs and under the other alternatives.

28

Another legal issue not mentioned in the DEIS is whether or not Section 10 of the ESA is an available option to the Public Utility Districts for Section 9 takings protection or whether Section 7 of the ESA is instead the proper vehicle. When the YN first entered into negotiations with the Public Utility Districts on the HCPs, the Tribe had questions about whether or not Section 10 was an available option, but the Tribe's concern at the time was the substance of the negotiations. The parties never addressed the procedural issue. The YN assumed that if a deal could be negotiated, the parties could find the proper vehicle to make it work. We believe, however, that this stage of environmental review is the appropriate time for such an analysis to be completed.

29

The YN understands that the Section 10 permit process is available to non-Federal entities but is not available to Federal landowners such as the United States Forest Service. As the NMFS' and USFWS' HCP Handbook explains at page 1-4, the HCP process is "designed to address non-Federal land or water use development activities that *do not involve a Federal action* that is subject to section 7 consultation." (emphasis added). Furthermore, it provides, "Federal activities and non-federal activities that receive Federal funding or require a Federal permit (other than a section 10 permit) typically obtain incidental take authority through the consultation process under section 7 of the ESA. Id. Hydroelectric projects, though owned by a non-Federal entity, are intertwined with extensive federal actions, including licensing, conditions, rates, and generation. The YN believes that the DEIS must address the applicability of Section 10 to the Public Utility Districts' projects in order to determine whether Alternative 3 may even be chosen as the preferred alternative.

30

The DEIS Lacks Meaningful Analysis of Survival, Recovery and Rebuilding

Under Section 10 of the ESA, an HCP must explain the impact that the proposed take will have on listed species. 16 U.S.C. § 1539(a)(2)(A)(i). See also 50 C.F.R. §§ 17.22(b)(1); 17.32(b)(1); 222.22. Under the National Environmental Policy Act (NEPA), agencies are

31

required to take a "hard look" at the consequences of their actions before acting. Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 249 (1989). This requires more than broad or general statements about risk, especially when more detailed information could be provided. See Neighbors of Cuddy Mountain v. United States Forest Service, 137 F.3d 1372, 1380 (9th Cir. 1998).

32 The YN believes that the DEIS fails to take the required hard look at impacts on anadromous fish and other trust resources. Neither the HCPs nor the DEIS present adequate quantitative detail of how listed species would be impacted by the HCPs. Furthermore, the DEIS does not do so under the other alternatives. The DEIS mentions the Quantitative Analysis Report (QAR) conducted by the NMFS, but does not incorporate the analysis into the alternatives. The
33 reviewer of the DEIS is left without any idea of how each of the alternatives actually compares in terms of survival and rebuilding benefits.

34 In the discussion of the No Action alternative, the DEIS states, "[e]xisting measures however, may not prevent the extinction of listed species." DEIS at 2-49. However, the discussion of the other alternatives fails to provide analysis of whether or not they will be an improvement and not also lead to extinction. The DEIS states that implementation of the HCPs would result in an increase in survival levels, but fails to explain what that means in terms of ESA standards or FPA requirements. DEIS at 4-39. According to NMFS's own data in the QAR, measures in addition to those set forth in the HCPs will be necessary for recovery, yet such information is not adequately addressed or analyzed in the comparison of alternatives. The
35 QAR report at ii states, "Even under the most optimistic scenarios . . . regarding future survival rates and the effectiveness of supplementation, additional survival improvements beyond those projected for the draft HCP actions would be necessary to achieve extinction risk/recovery criteria." This information should be analyzed in the DEIS.

36 The DEIS also does not account for the QAR's statement that meeting the HCP standards and off-site mitigation "would fall short of meeting survival and recovery criteria under the assumptions that 1980-present conditions will continue." QAR at iii. Therefore, according to the QAR, additional measures are going to be required for recovery, but such measures are not required or allowed by the HCPs. If something more than the HCPs is required, then Alternative 2 would be the only avenue for providing it. The DEIS must address this omission and include meaningful analysis across all of the alternatives.

37 As NMFS provides in the "Recovery" section of the NMFS VSP, the NMFS, States, Tribes and many other stakeholders have an interest in the recovery of salmon populations to the level that the populations can support "sustainable harvest or other 'broad sense' recovery goals." NMFS VSP at 34. NMFS provides that where a certain level of harvest may have an affect on the population's sustainability, NMFS could use VSP guidelines "to help determine the population abundance, productivity, diversity, and structure that would be required." Id. The YN would accordingly like to see the NMFS take into consideration the factors that led to the initial decline of the salmon and provide analysis that examines the impact that the various alternatives would have on the sustainability of the salmon populations and the ability of such populations to meet broad (beyond mere ESA) recovery goals.

The Geographic Scope of the DEIS is Inadequate

Use of the proper geographic scope in an environmental impact statement is paramount to assuring that the consideration of effects on the environment are adequately considered and addressed. The scope of environmental review is supposed to take into consideration three types of actions: (1) actions that may be connected (includes actions that are closely related, would
38 trigger other actions that require environmental review, or interdependent parts of a larger action); (2) cumulative actions; and (3) other similar actions (those that have reasonably foreseeable similarities, such as timing or geography). 40 C.F.R. § 1508.25. Under this requirement for determining scope, it is apparent that the scope of the DEIS is too limited.

Consistent with the concepts of aquatic systems and the operation of hydroelectric projects, the scope of the environmental review in the DEIS should at least include tributaries in the mid-Columbia Basin, upstream federal projects, the Lake Chelan Dam, downstream projects operated by Grant County Public Utility District, the Vernita Bar, and the Hanford Reach. The three hydroelectric projects at issue cannot be plucked out of the geography and their impacts on downriver systems ignored. Furthermore, power operation upstream of Wells, Rocky Reach and Rock Island affect anadromous fish survival, flow management and water quality at those projects.

In its scoping comments, the YN advocated that the scope of the review should include the entire mid-Columbia River Basin from the Yakima River to Roosevelt Lake. However, much of the benefit of salmon recovery in the Columbia Basin will accrue to the Columbia River
39 tribes in terms of expanded harvest opportunities at usual and accustomed fishing places in Zone 6 (Bonneville Dam to McNary Dam). Accordingly, the geographic scope of the DEIS should be expanded to account for the relative effects on the proposed alternatives on treaty fisheries in this area. See also discussion of Baseline below.

The DEIS Does Not Adequately Address or Analyze Cumulative Effects

Under NEPA, an environmental impact statement must contain consideration and analysis of cumulative effects. Cumulative impacts are effects from "the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time." 40 C.F.R. § 1508.7.

The YN, in its Scoping Comments on the HCPs, asked for such consideration and
40 analysis, but the DEIS does not adequately accomplish this. See DEIS at 4-6—4-47. The Tribe believes that the NMFS should have considered factors for decline throughout the entire life histories of each species, including effects that fall outside of the geographic scope of Alternative 3. Furthermore, the analysis should have included cumulative and synergistic impacts from the
41 Federal Columbia River Power Systems operations and all five of the mid-Columbia Public Utility District Dams (Wells, Rocky Reach, Rock Island, Priest Rapids, and Wanapum).

Additionally, the results presented in the DEIS reinforce the YN's concerns that an inability to enforce operations at federal dams or to impose environmental conditions are assumed in the
42 QAR model. Therefore, we fear that the effectiveness of the HCP measures cannot be assured. In order to effectively give consideration to cumulative effects as required by NEPA, the Tribe believes that the NMFS must provide a review and analysis of no less than what we requested in our Scoping Comments.

The DEIS Lacks a "Reasonable Range of Alternatives."

The NEPA requires that environmental review contain a reasonable range of alternatives. See 40 C.F.R. §§ 1502.14. Agencies are required to "[s]tudy, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources." 42 U.S.C. § 4322(2)(E). The discussion of the alternatives is the "heart" of the NEPA process. 40 C.F.R. § 1502.14.

The DEIS offers as its only alternatives a general Section 7 process and the HCPs (along
43 with the No Action alternative, which we address below). The YN does not find this to be a reasonable range of alternatives to meet NEPA requirements. The YN asked for additional alternatives in the Tribe's Scoping Comments, specifically that the NMFS include as alternatives three options that cannot realistically be pursued under the HCPs: drawdown, dam removal and non-power operations. The DEIS states that these alternatives do not merit further consideration,
44 but offers no satisfactory explanation for why these alternatives were not given analysis. DEIS at 2-45—2-48. This deficiency must be remedied and proper analysis be included in the environmental review, particularly in light of the NMFS' findings, as reported above, that the HCPs fall short of what would be required for ESA survival and recovery, let alone what is required under the United States' trust obligation to the Tribe.

The No Action Alternative Is Inadequate

The NEPA requires that a No Action alternative be included in an Environmental Impact
45 Statement. See 40 C.F.R. § 1502.14(d). However, the way in which the No Action alternative is presented in the DEIS misrepresents the existing situation and sets it up so that it cannot be given serious consideration. For example, the discussion of the No Action alternative completely omits statutory authorities at relicensing. This is particularly key relative to the Rocky Reach project, which is currently going through the relicensing process. In addition, Section 1.7.3.1 of the DEIS references the settlement agreements under the Mid-Columbia Proceeding, but the analysis of the No Action alternative does not fully describe the settlements, cross-reference
46 them throughout, or analyze the level of species protection provided through the settlement agreements and coordinating committees. NMFS should reframe the No Action alternative so that it accurately represents the actions that may be taken under the existing license, settlement agreements and statutory authorities.

By failing to take into consideration the activities of the coordinating committees under the settlement agreements, the No Action alternative and the DEIS in general also fail to adequately consider the interests of the Tribe, to which the NMFS has a trust responsibility. The

Tribe is a party to the Mid-Columbia proceeding and has a place in the coordinating committees, which allows the Tribe to exercise its involvement in co-management of the Tribe's trust resources. If the HCPs are put into place, with the idea that the HCPs will supercede these settlement agreements, the fishery-related signatories to the HCPs become a new coordinating
47 committee. See DEIS at 1-9, 1-15. However, if the Tribe is not able to sign the HCPs due to a lack of bargained-for consideration and assurances from the federal government, then the Tribe's participation in co-managing its trust resources may be affected. This should be addressed in the No Action alternative and factored into the comparison of the other alternatives.

The Comparison of Alternatives 2 and 3 Is Inadequate

The DEIS creates the illusion that Alternatives 2 and 3 are very much alike and neglects to highlight the very real and substantive differences between them. The DEIS also unfairly
48 downplays certain benefits of Alternative 2 in order to emphasize certain provisions of Alternative 3, making Alternative 3 seem like the better choice even though it may not be.

For example, the DEIS states that NMFS would require measures for tributary habitat
49 improvement under Alternative 2 just as such improvement would be required under Alternative 3. See DEIS at 4-32—4-33. (Note that elsewhere in the DEIS it states that tributary enhancement is only provided by Alternative 3. See, e.g., DEIS at 4-77). However, the DEIS provides no analysis of whether the tributary habitat improvements provided through Alternative 3 are even adequate, or whether the funding proposed is adequate to accomplish what is
50 necessary for ESA requirements. The DEIS also does not discuss whether greater protection could be provided under Alternative 2, as it most likely could were it needed to provide a measurable benefit to the fish.

The DEIS downplays Alternative 2 and underscores Alternative 3 by asserting that
51 Alternative 2 would only protect ESA-listed fish while Alternative 3 would provide additional protection for non-listed species. However, measurements under Alternative 3 are likely to use target species to represent the level of protection being provided to the other species. See DEIS at 2-41 (discussing the PUDs proposed use of "representative survival studies" on yearling Chinook and steelhead). Given the complications with measuring survival of listed as well as non-listed species, the level of protection provided under either alternative is likely to be gauged off of target species. See discussion of measurement and evaluation below. Furthermore, non-
52 listed species such as lamprey and sturgeon, which are not included in the HCPs, would need to be considered at relicensing under the Federal Power Act and are currently taken into account by members of the Mid-Columbia coordinating committees. Listed species, such as bull trout, are also not covered by the HCPs, but would have to be addressed under Alternative 2, and
53 Alternative 3 would most certainly affect USFWS' ability to meet its federal responsibilities for that and other listed species not covered by the HCPs. Therefore, it is not accurate to assume that Alternative 3 will provide a broader range of protection than the other alternatives.

Another concern that the Tribe has with the DEIS is that it repeatedly asserts that Alternative 2 would be thwarted by indefinite delays. See, e.g., DEIS at 1-15. Because the DEIS uses "the speed at which each alternative could be implemented" as criteria for comparing

Alternatives 2 and 3, DEIS at 2-49, it appears that the "indefinite delays" are used to weigh against Alternative 2 in favor of Alternative 3. However, the YN believes that "indefinite
54 delays" under Alternative 2 are theoretical and impracticable, and as such, should not be used to justify a decision in favor of Alternative 3. The absence of protection from the Section 9 takings prohibitions could be a significant motivator for the Public Utility Districts to seek Section 7 protection in the absence of a Section 10 permit. Furthermore, Alternative 3 may likewise suffer theoretical delays if the tools used by the Public Utility Districts in the HCP toolbox fail to provide improvement in survival and recovery or if the Public Utility Districts believe they have met a standard or wish to use a specific tool even though all others disagree,[1] yet such delays are not factored into the analysis of Alternative 3.

55 Finally, the Tribe believes that the DEIS improperly includes drawdown as an option under Alternative 3, which further attempts to blur the distinction between Alternatives 2 and 3, though drawdown is really only an option under Alternative 2. We discuss this further below.

Under Alternative 3, the DEIS Should Address Limits on Statutory Authorities and the Trust Responsibility.

56 The HCPs that make up Alternative 3 may place significant limits on the statutory authorities of federal agencies and on the ability of such agencies to comply with their trust responsibility to the Tribe, yet the DEIS fails to consider or assess these limitations. For example, under the dispute resolution provision of the HCPs, the NMFS's decision-making authority on scientific information is forfeited to a neutral third party. Furthermore, the No
57 Surprises assurance prohibits NMFS and other agencies from exercising authorities and responsibilities by pre-determining what measures are required and prohibiting the imposition of additional mitigation.

58 If NMFS chose Alternative 3 as its preferred alternative, NMFS would predetermine the operations of the hydroelectric projects before the FERC could determine whether the amended or new license it issues complies with the Federal Power Act and FERC's trust responsibility. At relicensing, all of the participating state and federal agencies, such as the Washington Department of Ecology, FERC, USFWS, and the Bureau of Indian Affairs, would be constrained from exercising their statutory authorities to require what they believe is necessary for protection, mitigation and enhancement under the Federal Power Act or for meeting their trust obligation to tribes. These limitations on the authorities and responsibilities of other agencies should be addressed in the DEIS.

[1] As a case in point, the Tribe's representatives (and others as well) on the Mid-Columbia Coordinating Committee (MCCC) are currently experiencing difficulty with Chelan Public Utility District, who asserted at an April 2001 MCCC meeting that it can meet a 95% survival rate by operating its bypass system, providing a $5 million habitat mitigation fund, and generating electricity with water that would otherwise be used for spill. The Tribe's representatives have been given very little to no input on the decision-making and have asserted that there is no scientific information being presented to demonstrate that Chelan has reached a reasonable conclusion. Thus, if history is any indication, Alternative 3 is likely to be thwarted by even greater delays than those imagined under Alternative 2.

The No Surprises Assurance Is Inappropriate for These HCPs

The No Surprises rule was adopted in order to provide certainty for landowners that additional land or other mitigation (financial resources) would not be required of them for the protection of listed species except in "extraordinary circumstances." Instead, the obligation for providing the necessary, additional mitigation would rest with the federal government or other non-federal landowners who lack their own similar assurances under the ESA. For example, if non-federal landowner "A" has an HCP that fails to provide adequate habitat for spotted owls, Landowner A's neighbors, the United States Forest Service and non-federal landowner "B," would have to keep their lands available for the habitat needed by the owls.

In the aquatic situation such as the Mid-Columbia HCPs, however, there are no "neighboring landowners" to be responsible for habitat or other protective needs. For example, even if the federal projects upstream and the non-federal and federal projects downstream of the Chelan and Douglas were required to provide 100% survival in order to make up for declines allowed by the HCPs, the fish and the water nevertheless must pass through the Chelan and Douglas projects. To roughly translate this to the land-based HCP as outlined above, it would be as if Landowner A's HCP allowed him not only to destroy owl habitat, but to shoot at all owls that flew over his property on their way to the habitat being preserved by the United States Forest Service and Landowner B.

59 The river and the hydroelectric system are so interconnected that there are not adequate "neighbors" to make up the difference if needed by the anadromous fish. The Tribe is concerned that the application of the No Surprises assurance to a river-based HCP may result in the NMFS seeking to restrict the Tribe's fisheries. However, the Tribe would view this as a breach of fiduciary duty and a violation of federal case law. Therefore, the DEIS should provide an analysis of the feasibility of the No Surprises assurance to the HCPs and the extent to which shortcomings in protective measures could be met, keeping in mind the federally recognized and protected resource rights of the Tribe and the United States' trust responsibility.

No Net Impact Under Alternative 3 is Misrepresented in the DEIS

60 The YN believes that the "100% No Net Impact" (NNI) standard of the HCPs in Alternative 3 is misrepresented in the DEIS, which fails to take into account recent scientific information. NNI represents 91% dam passage survival (which includes a 95% juvenile dam passage survival component) and 9% mitigation (7% via hatchery compensation and 2% via tributary improvements). .The 100% NNI concept was created with the idea of making the dams "invisible" to the fish. The concern that the Tribe expressed in its Scoping Comments is that the components of NNI do not add up to 100% because the gains in survival may be exponentially additive but not linearly additive, and the components consist of different "currency" by mixing juveniles with adults.

61 The 9% mitigation requirement fails to assure the benefits that it is presumed to provide. The parties to the HCPs are not even thinking about measuring the 2% habitat component, but instead plan to just assume that the funds will provide a 2% benefit. There has been no analysis

of whether the proposed funding levels will be capable of providing the presumed benefit. The 2% number is in fact pure fiction. The YN is very concerned that the funding levels are inadequate. The bulk of the funding for the tributary plan was to come from Grant County Public Utility District when it was involved in the HCP negotiations. Once Grant pulled out of the process, the total amount of the tributary fund was greatly reduced, even though it started out much lower than many of the fishery parties thought necessary to confer a 2% benefit. Subsequently, Douglas County Public Utility District's share of the funds may be reduced in half of what it originally proposed to provide. In the YN's opinion, the tributary fund is thus left much under-funded. In its Scoping Comments, the Tribe requested a watershed analysis to further explore this concern. The DEIS should provide such an analysis in order to determine whether the funding will provide the needed benefit.

62

63 There also exists a lack of certainty regarding the 7% hatchery compensation level. If the Public Utility Districts are not allowed to meet the 7% component through hatcheries, then there will be a deficit in the required mitigation. NNI would not be achieved, but the HCPs would allow the hydroelectric projects to continue taking fish. The DEIS takes this in account in some places, but fails to address it in others, and the lack of obtaining the 7% is not factored into any analyses of Alternative 3 that we could locate. The DEIS also fails to provide evaluation of the adequacy of the proposed mitigation plan as the Tribe requested in its Scoping Comments.

64

65 Further, there is reason to believe that adult losses are much greater than the 2% estimated, yet the HCPs require mitigation for only 2% through either habitat or hatchery, neither of which are guaranteed. The DEIS should provide analysis of actual adult losses, examine the adequacy of the adult passage plans, and address mitigation for adult losses under the various alternatives.

66 Despite the lack of analysis and the problems with the concept of 100% NNI, the DEIS frequently states that the HCPs "*guarantee* 100 percent no net impact for each of the Plan species." See, e.g., DEIS at 2-54 (emphasis added). The DEIS also lacks any analysis as to whether 95%, 91% and 100% NNI will meet ESA requirements and the requirements for protection, mitigation and enhancement under the Federal Power Act. These and other concerns about the NNI standard were set forth in the Tribe's Scoping Comments, but were not considered or analyzed in the DEIS as requested. The Tribe hereby reiterates its request that these NNI issues be addressed in the DEIS, as well as the following:

67

- 68 Assess potential impacts on species within the first five years of the HCPs, during which time the NMFS and USFWS cannot prescribe or preempt the plans of the Public Utility Districts;
- 69 Analyze and explain the biological basis for the draft HCPs' assumption that 91% survival + 7% hatchery mitigation + 2% tributary mitigation are additive to guarantee zero impact on the species;
- 70 Examine the relationship between the NNI standard and long-term stock viability;

71 • Analyze whether or not the proposed measurement of the performance standard for 95% Juvenile Dam Passage Survival, by measuring juvenile survival over only 95% of the run, ensures a juvenile passage mortality of only 5% such that the draft HCPs address full mitigation for take;

72 • Examine passage impacts to anadromous fish and lamprey and descaling injuries (particularly on sockeye) if screens are installed and assess whether such impacts are accounted for within the NNI standard;

73 • Determine what impacts may occur during the time period that elapses before the Public Utility Districts actually meet the proposed survival requirements and analyze whether those impacts can or will be appropriately mitigated;

74 • Determine impacts on the species should the survival goals never be reached during the term of the HCPs;

75 • Assess impacts on spring migrating Chinook salmon if exempted from 95% Juvenile Dam Passage Survival as planned (See Wells Agreement at Sec. IV(1)(b)); and

76 • Provide an accurate evaluation of losses and determine whether the mitigation proposal is supported by adequate data to ensure no unmitigated take.

SPECIFIC COMMENTS

Drawdown

77 The YN is very concerned about the misrepresentative nature of the DEIS' references to drawdown in the comparison of the alternatives. The DEIS states that the Public Utility Districts, the NMFS and the USFWS can mutually agree to drawdown (or dam removal or non-power operations). See, e.g., DEIS at 2-33. This is true under the HCPs *only if* NNI has not been achieved and maintained after 20 years has elapsed but the Public Utility District is otherwise in compliance with the Section 10 permit. See, e.g., Wells Agreement at Sec. II(2)(a)(ii). Furthermore, the topic of agreement among the Public Utility District, the NMFS and USFWS is not to *implement* drawdown, but to allow the NMFS to pursue such a measure. See id. There is *no* ability to use drawdown even if, though NNI has been achieved, the anadromous fish resource is not rebuilding and the Public Utility Districts' hydroelectric projects are a significant factor in the failure to rebuild. See id. at Sec. II(2)(a)(i).

78 Instead, the HCPs provide, under the Assurances sections, that drawdown is precluded from consideration: "[E]ach Party during the term of this Agreement *will not advocate for or support* additional or different fish protection measures or changes in Project structures or operations other than those set forth in this Agreement. This Agreement *does not include* as Measures: partial or complete *drawdowns*, partial or complete dam removal, and partial or complete non-power operations." See, e.g., id. at Sec. IX(10) (emphasis added). Furthermore, the Public Utility Districts party to the HCP negotiations were adamant that none of the other parties to the HCP negotiations even breathe a word about drawdown, to the extent that the parties joked that they could not say the word "drawdown" at a cocktail party. Thus, based on the intent of the Utility Districts and the language of the HCPs, drawdown is not at all an option under Alternative 3.

79 By lumping drawdown into Alternative 3, even though the HCPs basically forbid its use, and pretending that Alternative 3 is no different on this issue than Alternatives 1 or 2, blurs one of the more substantive distinctions among the alternatives. The YN opposes the NMFS's approach on this issue.

80 Furthermore, the DEIS states that drawdown could not be required under Alternative 2 except at the time of relicensing. DEIS at 4-29. If the NMFS requires drawdown as a reasonable and prudent alternative under the Section 7 process, but the license is not amended to include the drawdown requirement, then the Public Utility Districts would be in violation of the ESA. Perhaps there is a reason why drawdown can be required only at relicensing, but the Tribe is not currently aware of such. The YN thus requests a detailed explanation. Even if the DEIS is correct, the possibility of drawdown exists for each of the three projects under Alternative 2 because all of them will be relicensed at some point during the next 50 years (which would be the term of the HCPs).

81 Drawdown must therefore be given serious consideration under Alternative 2 and should also be analyzed as its own alternative as the Tribe requested in its Scoping Comments. The YN understands that the DEIS finds drawdown to be an unrealistic alternative, DEIS at 2-48, yet such a blanket statement without any discussion or analysis is inadequate. Additionally, the emphasis that the DEIS places on the ability to use drawdown as a tool under Alternative 3 (though false) indicates that it is not as valueless as it is made to seem under the other alternatives. These problems with the approach to drawdown must be accurately resolved in the revisions to the DEIS.

Measurement and Evaluation of the HCP Permit Obligations

The YN believes that the measurement and evaluation provisions of the HCPs are key to determining whether the Public Utility Districts are meeting the permit obligations and what impacts the dams are having on the anadromous fish resource. However, there are no methods to which the parties agreed for measuring the standards or for what species and life histories to study. The DEIS states, "There is currently no methodology that all parties support for determining the survival of adult fish through the projects." DEIS at 2-41.

82 If measurement and evaluation cannot at least initially be decided, it could result in years of delay where the Public Utility Districts fail to actually meet the standard but are allowed to take species nonetheless. Similarly, there is no standard or method for measuring the "steady process" required within the first five years of the HCPs. Due to the uncertainties in measuring
83 the standards, and the assumption of certain components of NNI (see above), it could be next to impossible to determine whether or not the Public Utility Districts are achieving the proposed NNI standard on which the permit would be based. The DEIS should squarely address this issue.

Baseline

84 The YN believes that the DEIS must discuss the impacts that Alternative 3 would have on the Tribe's treaty resources. In order to do so, it is imperative that the baseline from which the improvements or impacts are measured is proper. However, the DEIS uses Alternative 1 as the

baseline condition, DEIS at 2-22, which fails to account for whether existing mitigation or compensation levels are adequate and presupposes that existing degraded conditions do not need to be considered.

The DEIS states,

> Mitigation measures for these impacts have already been implemented as part of the existing licenses. Prior activities are not considered an action subject to additional mitigation beyond license requirements unless they are considered to cause a continuing "take" of a listed species as defined under the [ESA]. Existing hatchery production levels are initially assumed to provide adequate compensation for original inundation by the projects. Therefore, the baseline is considered to be the existing conditions. These baseline conditions also form the basis for determining what effect continuation of the existing conditions would have on listed species. The baseline conditions that existed as of January, 1997, would be used to determine if progress were being made to increase the survival of the Plan species through the implementation of the HCPs.

DEIS at 2-23.

85 The YN disagrees with the DEIS's assumptions. Use of the currently degraded environment as the measuring stick for determining what harms and benefits the alternatives will have on treaty resources fails to take into consideration the fact that the development of the hydroelectric projects set in motion a decline in fish populations that is still being felt in the Basin and that is still negatively impacting tribal trust resources. Instead, the Tribe requested in its Scoping Comments that the DEIS use a natural river baseline. The 1995-1998 Biological Opinion on the Federal Columbia River Power System, drafted by NMFS, was of the opinion that an accurate baseline relative to considerations about hydroelectric dams examines continuing effects of previous degradations. It defines the environmental baseline as the effects of the proposed action as added to past and present impacts of all Federal, State, and private activities in the action area, which is itself defined as all areas directly or indirectly affected by the federal action and not merely the immediate area involved in the action. See Biological
86 Opinion at 12. As NMFS has done in the past, it should recognize in the DEIS that the nature and extent of ongoing impacts must be analyzed in a systematic way.

Lamprey and Sturgeon

87 The YN believes that lamprey and sturgeon should be given greater consideration in the DEIS. Comments about lamprey and sturgeon are sprinkled throughout the DEIS, but the analysis of the impacts or benefits to these species is inadequate.

88 For example, the DEIS states in general terms that lamprey and other species (trout) are "expected to benefit" from the tributary improvements that would take place under the HCPs, but the DEIS contains no data or analysis to support such an assertion. Though not a species listed under the ESA, Alternative 2 may have benefits or impacts on lamprey, which are not mentioned

in the Environmental Consequences discussion about Alternative 2. Because lamprey are an important part of tribal culture and a subject of the federal government's trust responsibility, the Tribe is very concerned that such a species receives so little attention in the analysis.

89 Sturgeon is likewise given very little attention in the DEIS. Though listed as a resident fish resource, DEIS at 3-47, it is not discussed under the life histories section, DEIS at 3-47—3-52, and is not even cross-referenced in the Environmental Consequences Sections that address
90 fishery resources under Alternatives 2 or 3. Though little may be known about lamprey and sturgeon, as the DEIS suggests, DEIS at 4-27—4-28, consideration of the impacts and benefits to these species, based on analysis, should be included under all of the alternatives.

Long-Term Risks

91 The YN is concerned that not enough deliberation has been given to the long-term risks of Alternative 3. See DEIS at 4-77. We believe that NMFS should place greater weight on the risk of uncertainty over the 50-year period of the proposed Section 10 permit, especially because the NMFS recognizes the "limits of existing information." Id. NMFS should also assess the lack of ability to apply greater protective measures relative to long-term risks given the No Surprises
92 assurance. Even though the HCPs contain adaptive management provisions, the framework of the HCPs is locked in for 50 years and the federal resource agencies will be prohibited from requiring higher survival levels if needed and if technology allows.

93 The DEIS also fails to assess the consistency of the alternatives under the concept of a normative river and multi-species restoration, determine risks posed through a probability of assumptions being mistaken over long periods of time, address how the alternatives may select against certain species and life histories, and examine opportunities for and feasibility of reintroducing Coho. The Tribe requested in its Scoping Comments that these risk issues be addressed in the DEIS and reiterates its request here.

Measures for Adult Fish

The HCPs fail to adequately address adult passage and survival standards and measures, which are in turn inadequately addressed in the DEIS. The adult anadromous fish issue was a significant sticking point during the HCP negotiations, with the result being inadequate provisions for adult in the HCPs. Though the HCPs take into account some adult losses (an assumed 2% that figures into the 9% mitigation component of No Net Impact), the actual amount
94 of adult losses has not been quantitatively measured. Such a lack of measurement is likely to allow the Public Utility Districts to ignore operational and structural fixes under Alternative 3 that could be made at their projects to benefit adults. This factor should be taken into account in the DEIS analysis and comparison of the alternatives, particularly because returning adults that make it to the spawning grounds contribute significantly to the next generation of juveniles. Adults must not be forgotten or ignored in the environmental review. Furthermore, under each
95 of the alternatives, the DEIS should provide a discussion and analysis of measures and standards that could increase adult passage survival, such as improved passage time, reduction of adult fallback rates, and limits on power peaking operations.

Summer/Fall Chinook

96 The Tribe believes that the DEIS should not lump the summer and fall Chinook together as one species. Under the HCPs, at the request of the tribes participating in the negotiations, the parties made a conscious decision to list the species separately. For example, the Wells Agreement defines "Plan Species" as "spring, summer and fall Chinook salmon." Wells Agreement at Sec. XIII(11). The Tribe has previously provided extensive comments to the NMFS on the proposed listing of summer Chinook demonstrating clear distinctions between summer and fall Chinook in run timing, spawning locations and flesh quality. Yakama Nation. 1993. Comments on the Proposed Listing of Mid-Columbia Summer Chinook Salmon Under the Endangered Species Act. Yakama Nation Fisheries Resource Management Program. p. 19. The YN thinks that the analysis contained in the DEIS regarding effects on the species should thus treat each race as independent of the other.

Evolutionarily Significant Units (ESU)

97 The DEIS fails to clearly identify the standard by which the status of the ESU is measured. We understand that NMFS has established by rule that the Upper Columbia River (UCR) spring Chinook ESU is comprised of naturally-spawning spring Chinook returning to
98 tributaries above Rock Island Dam, and UCR steelhead as those above Priest Rapids Dam. The DEIS appears to establish separate measures and standards for the recovery of three tributary populations in the Wenatchee, Entiat, and Methow rivers. The geographic place and biological terms that will be used to measure progress toward recovery of these ESUs should be clearly
99 described, along with any applicable law or policy. The YN also requests that the NMFS provide an explanation of its authority to manage units smaller than the ESUs.

Economic Impacts on Tribes

100 Section 3.7 of the DEIS addresses socioeconomic impacts on populations, employment and income. However, the Tribe believes that consideration should be given to the impacts on Tribes for loss of fishing due to reductions in the Tribe's treaty resource. The wealth of salmon that the Tribe used to enjoy has been redistributed to non-tribal persons or entities in the form of irrigation, navigation, and flood control, to name a few. This redistribution has resulted in significantly high poverty rates and death rates for tribal members above those of the non-Indian population or non-tribal communities. See CH 2 M Hill. 1999. Human Effects Analysis of the Multi-Species Framework Alternatives (prepared for the Northwest Power Planning Council).

Specific to the mid-Columbia hydroelectric projects, the dams have been recognized as taking away sustainable wealth from the tribal people. Id. The YN's tribal members now take less than 10% of the fish that they used to take in traditional salmon harvests, which significantly contributes to the YN's low per capita income (43% of that of the State of Washington) and high
101 poverty levels(42.8% compared to 10.9% in Washington). Id. Every juvenile salmon that survives the hydroelectric system and returns as an adult brings back to the Tribe some of the river's wealth for tribal economy and culture. The DEIS alternatives must therefore be evaluated

as to their effects on tribal culture and economics, and their ability to redistribute the river wealth back to tribal peoples.

Scoping Comments

The YN wishes to incorporate by this reference anything not specifically addressed in these comments, but addressed in the Tribe's Scoping Comments filed in conjunction with the Columbia River Inter-Tribal Fish Commission and the Confederated Tribes of the Umatilla Indian Reservation. The comments were filed on February 5, 1999 and are part of the Scoping record. We also point out that the Tribe has not yet received a response from the NMFS on its Scoping Comments, which were never specifically addressed in the scoping meetings. 102

CONCLUSION

Based on the above comments, the YN believes that the NMFS should immediately withdraw the DEIS. 103 The HCPs need finalization before environmental review should take place. At the least, the DEIS is in need of significant revisions and additions as described above. In the meantime, 104 the YN believes that the only option available is to immediately begin Section 7 consultation in order for the Public Utility Districts to receive protection under the ESA. Furthermore, the stakeholders in the region should be allowed to participate in the relicensing of the Rocky Reach project without the constraint of the HCP, 105 since there is a complete lack of closure and absence of an agreement.

We again thank you for the opportunity to present the comments of the Yakama Nation on the DEIS. If you have any questions, please contact Tim Weaver at 509/575-1500, Starla Roels at 503/242-1745, or Steve Parker or Bob Rose at 509/865-6262.

Sincerely,

Tim Weaver /by SKR

Response to Comments

Water Quality

Comment 1 *Several commenters questioned the statement that the Mid-Columbia River projects have limited influence over water temperatures in the reach. They requested data to document the potential influence of the projects on water temperature and travel time, as well as monitoring requirements under the action alternatives to determine the potential effects on critical habitat and fish survival. It was also suggested that operational changes or changes to the water release schedule at Grand Coulee Dam could be used to regulate water temperatures.*

Response 1 Statements about the influence of Mid-Columbia River hydroelectric projects on water temperatures were based on literature cited in FEIS Section 3.3.2.1, Project Area. The spatial and temporal distributions of temperatures within the Mid-Columbia River were examined in the Rocky Reach reservoir during the critical period of August 2000 (Parametrix, Inc. and Thomas R. Payne & Associates 2002). Vertical profile measurements in different areas of the reservoir confirmed the absence of thermal stratification, as expected in these run-of-the-river reservoirs. Even in the forebay, the deep waters were no more than 0.3° C cooler than surface waters. Because the Mid-Columbia River reservoirs do not provide storage, the waters are well mixed and temperatures are relatively uniform. Also, the temporal differences between daily minimum and maximum temperatures were rarely more than 1° C. Because of the lack of temperature variability within the reservoirs, modifications to Mid-Columbia River dam operations would not have a substantive effect on the water temperature regime. Although the operation of Grand Coulee Dam is outside the scope of this EIS and the alternatives, revisions regarding Grand Coulee operations and cold water releases were made to FEIS Section 3.3.1.1, Project Area. The greatest degree of modifying dam operations, reservoir drawdown, is addressed under Alternative 2 (FEIS Section 4.3.2.2, Alternative 2), and measurable changes in water temperature were not expected to occur.

There are no reliable pre-dam temperature data to determine if the observed differences are a natural function of solar warming or are in some part attributable to the reservoir operations. Chelan County PUD has recently begun a project to model water temperature conditions in Rocky Reach reservoir to provide more information on this issue. Pre-project temperature conditions will be modeled by re-creating historic width-to-depth ratios for this Columbia River reach and examining the change in topographic shading effects from lower water levels. Water quality monitoring would be the same for all alternatives, as none of the alternatives would affect the requirements of meeting Federal or State water quality standards. Rocky Reach water temperature monitoring data has been added to FEIS Section 3.3.2.1, Project Area.

Flushing rate data were added to FEIS Section 3.2.10.2, Project Area Rearing. Beak Consultants, Inc. and Rensel Associates (1999) reported mean flushing rates of 1.5 days in the Wells Dam reservoir and 1.8 days in the Rocky Reach reservoir. Average travel time in the river without the dams is unknown; however, the increased size of the river cross-section resulting from raising water levels upstream from the dams reduces river velocities. Chelan County PUD (1991) estimated that a 3-foot increase in the Rocky Reach reservoir elevation would result in velocity reductions of 0.04 to 0.06 feet per second, depending on river flows. Therefore, increased travel times through each of the reservoirs since construction of the dams is likely on the order of hours rather than days.

Although there is no ability to spill colder deep waters at Grand Coulee, relatively cool water is released through the turbines, which reduces maximum summer temperatures. However, diverting generation to Grand Coulee is outside the scope of alternatives evaluated in this FEIS. Creating shade at the mouths of tributaries is an option for review by the tributary committees in identifying projects to fund through the Tributary Conservation Plan.

Although the DEIS included a discussion of critical habitat that was designated for spring-run chinook salmon and steelhead in the Mid-Columbia River region, Judge Colleen Kollar-Kelly of the D.C. District Court entered the consent decree resolving claims in the National Association of Homebuilders' litigation regarding critical habitat designations for 19 Evolutionarily Significant Units previously filed with the court. That decree vacated the critical habitat designations and remanded them to NMFS for new rulemaking. As a result, critical habitat designations no longer have independent legal significance. However, if critical habitat is redesignated prior to the full implementation of the HCPs, it will be included in the HCP biological opinions. Therefore, the adverse modification standard for essential features of critical habitat and the analysis of effects on critical habitat have been removed from the FEIS.

Regardless of the legal significance of critical habitat designations, NMFS must consider the effects on the listed species' habitat to determine whether an action is likely to jeopardize the species. In addition, the mainstem Columbia River is considered part of the Essential Fish Habitat for commercially harvested fish species covered by the Magnuson-Stevens Act. Therefore, the potential effects of the FEIS alternatives on anadromous fish habitat in the mainstem Columbia River are addressed in the FEIS.

Unlike the Snake River or lower reaches of the Columbia River, the middle reach of the Columbia River typically does not exceed 15º C prior to mid-June and rarely exceeds 20º C at any time during the summer (Columbia Basin Research 2002). Thus, any deleterious temperature effects on adult or juvenile anadromous fish or resident fish in the mainstem river resulting from the Douglas or Chelan County PUDs' projects are likely non-existent during the spring migration and negligible to extremely small during the summer and fall migrations.

Comment 2 *The EIS should explicitly state that the 120 percent saturation criterion is a special exemption for spilling water to aid in fish passage and that the criterion at all other times is 110 percent, and explain the implications. This waiver is granted because the benefits of moving fish downstream outweigh the potential impacts of total dissolved gas levels of up to 120 percent. Mitigation for the effects of spill on total dissolved gas levels or provisions for gas abatement efforts should be provided. The EIS should include upstream and downstream projects in relation to meeting the total dissolved gas water quality standards. The responsibilities and rights of the regulatory parties to enforce water quality standards under each alternative should be explained.*

Response 2 Pertinent sections of the FEIS were modified to explain the variable total dissolved gas standards (including FEIS Sections 2.3.2.1, Wells Hydroelectric Project; 2.3.2.2, Rocky Reach Hydroelectric Project; and 2.3.3.4, Rock Island Hydroelectric Project). FEIS Section 3.3.2, Water Quality of the FEIS provides more detail on water quality standards, including those for total dissolved gas. The effects of juvenile fish bypass requirements on total dissolved gas levels in the river are common to all alternatives. Neither action alternative relieves or alters any responsibility of the PUDs to meet State or Federal water quality criteria. Compliance with these laws is also a FERC license/relicensing issue, thereby providing other regulatory and management entities the ability to enforce water quality compliance issues under all the alternatives. The HCPs require the signatory parties to work together to address water quality issues (see Section 5 of the Wells HCP [Reservoir as Habitat and Water Quality] and Section 6.3

of the Rocky Reach and Rock Island HCPs [Reservoir Habitat and Water Quality), but do not establish the actions necessary to satisfy the Clean Water Act.

Upstream and downstream dams are considered in the cumulative effects of the alternatives provided in Chapter 5 of the FEIS, which includes total dissolved gas impacts. The PUDs have no control over the operation of upstream Federal projects.

Under the HCPs (Alternative 3), the HCP signatory parties recognize that total dissolved gas supersaturation is a cumulative effect of hydropower operations in the Columbia River and are committed to addressing these issues (see Section 5.3 of the Wells HCP [Reservoir as Habitat and Water Quality] and Section 6.3 of the Rocky Reach and Rock Island HCP s [Reservoir Habitat and Water Quality]). The PUDs and/or the coordinating committees would consider these restrictions when determining the appropriate measures for meeting the fish survival performance standards. Any impacts to fish survival related to exceeding water quality parameters would affect the ability to meet the total project passage survival standards set in the HCPs. In addition, any impacts to fish survival at downstream hydroelectric projects (for example, spill reductions due to increased total dissolved gas levels in the Wanapum Dam forebay) resulting from efforts to meet survival standards at the Douglas or Chelan County PUD projects would be similarly considered.

Turbidity and Erosion Mitigation

Comment 3 *Table S-3 states that if reservoir drawdown occurs, erosion and reservoir turbidity would initially increase over the short term and damage aquatic habitat conditions, with the greatest damage occurring during the first 4 to 7 years. The EIS should identify ways to mitigate these impacts if any exist. The EIS should discuss how the loss of natural turbidity due to the existence of the projects has contributed to the decline of salmon productivity.*

Response 3 The actual amount of erosion and resulting turbidity, and the consequent effects on aquatic habitat, are uncertain and were overstated in the DEIS. This has been revised in the FEIS. Moderate increases in turbidity may not have adverse effects on aquatic habitat in a river that was likely more turbid before upstream dams were built. Some areas of the shoreline are naturally or artificially armored with rock, and little erosion would be expected in those areas. More erosive shoreline areas would be seeded and/or treated with erosion control materials if drawdown occurred and excessive turbidity was predicted.

Although drawdown is identified as a potential option in the FEIS to improve fish survival rates, it is an option common to both action alternatives. As a result, a detailed evaluation of this option would not provide valuable information in the comparison of the alternatives. The FEIS also indicates that the environmental consequences related to a drawdown scenario are significant enough to require a more specific and detailed environmental review and NEPA analysis.

Comment 4 *The EIS should discuss plans to modify the projects or their operations to comply with water quality standards. Consideration of water quality effects, including opportunities for improvements, should be part of all bypass development plans.*

Response 4 None of the FEIS alternatives relieve or alter any responsibility of the PUDs to meet State or Federal water quality criteria. The use of spill may be restricted to meet the total dissolved gas criteria, to the extent necessary to achieve the HCPs' survival standards. Project operational or structural modifications made by the coordinating committees would likely consider potential water quality effects before implementation. Douglas County PUD has developed a bypass

system at the Wells Dam that reduces the amount of spill required to pass substantial numbers of fish and also meets the HCP juvenile project passage survival standard, thereby reducing the total dissolved gas levels downstream. Chelan County PUD is currently constructing a surface bypass system at Rocky Reach Dam that is expected to minimize the amount of spill needed to meet fish passage or fish survival criteria. Section 7 consultation with NMFS for this construction project was completed in 2002 (NMFS 2002a). However, evaluations at Rocky Reach Dam suggest that project operations typically result in little or no increases in total dissolved gas levels as water passes the project (Parametrix 2000b). Spill gate modifications are being evaluated at Rock Island Dam to improve fish passage efficiency while reducing spill volume requirements.

Biological Opinion and its Relationship to the EIS

Comment 5 *Several commenters suggested that the EIS should not be proceeding until the biological opinions are written for the projects. They expressed concern about being able to provide adequate review and comments on the proposed action and its effects unless the alternatives are disclosed in their entirety. If the biological opinion for the preferred alternative contains different or additional mitigation measures than what is provided in the EIS, commenters stated that a supplemental EIS would be required. It was also suggested that, if biological opinions were written for Rock Island and Rocky Reach dams, the framework of the alternatives would likely change.*

Response 5 Actions described in the FEIS represent the most likely measures to be implemented under Alternatives 1, 2, or 3 at this time. However, presupposing all potential measures or combinations of measures is not possible given the available information and the status of existing technologies. New technologies may be developed or a combination of measures not currently considered may eventually prove to be the most effective program for increasing survival of Endangered Species Act-listed or Plan species over the long-term. All of the information utilized by NMFS to reach a decision on issuance of the Section 10 permits has been disclosed in the FEIS.

Biological opinions will be issued for all dams regardless of which alternative is selected (although the biological opinions would be written at different times). The basic content would be similar for both action alternatives because the biological opinions would be based on the best available data. Many issues raised from comments on the DEIS were resolved through subsequent discussions amongst the PUDs, NMFS, and the other Joint Fisheries Parties during the fall/winter of 2001/2002. The resolution of these issues has been fully described in the revised HCPs and FEIS, and adequately identifies the most likely future alternatives for evaluation in both the FEIS and the biological opinions.

Although the additional negotiations did not result in substantial changes to the HCPs, the negotiations resulted in establishment and clarification of specific guidelines to assess and/or monitor the measures implemented at the projects to meet and maintain the standards identified in the HCPs. The negotiations also established additional and specific schedules for assessing the effectiveness of the HCPs for providing the necessary protection for all Plan species. The clarification of these issues was the direct result of comments received during the NEPA scoping meetings and the public comment period for the DEIS. The first page of each chapter in the FEIS provides a synopsis of the changes that were made and the rationale behind the changes.

Cumulative Effects

Comment 6 *The DEIS does not adequately address or analyze (1) connected actions, (2) cumulative actions, and (3) similar actions, as is required under the NEPA process. Some specific information*

requested for inclusion in the cumulative effects section was the effects of smolt outplanting on wild fish, entire life history of each species, navigational channel deepening project, a reach-based perspective, and inclusion of more fish species and more natural resources.

Response 6 The scope of the DEIS includes the three actions as described above in the comment. Connected actions occur within and between the projects. All the fish protection measures at each dam would be considered potentially connected actions and are addressed individually and collectively in the FEIS. Cumulative and similar actions (fish protection measures and environmental factors that could affect the listed species in the Columbia River system) are described in the Quantitative Analysis Report (QAR), a summary of which is included in Appendix E and Chapter 5 of the FEIS. The QAR incorporates the actions expected to occur in the Lower Columbia and Mid-Columbia River reaches (except for the hatchery supplementation provisions of the HCPs), as well as factors that affect the entire life cycle of the fish to assess cumulative and similar actions. Chapter 5 of the FEIS describes the cumulative effects analysis, which includes the hydropower projects throughout the Columbia River and the initiatives developed in the basin to address salmon and steelhead recovery.

Cumulative effects were shown for each resource in Chapter 4 of the DEIS (Environmental Consequences) under sections titled Columbia River System. To ease reader review of the cumulative effects, these individual sections have now been moved to Chapter 5 of the FEIS (Cumulative Effects). The QAR (Appendix E) includes survival through the total life history of the listed species and encompasses the overall geographic and environmental conditions that affect salmon and steelhead. This chapter includes discussions of harvest, hatchery production, habitat quantity and quality, and hydropower within the Columbia River Basin. Note that the mitigation proposed for the tributary habitat improvements represents program funding rather than specific projects. Therefore, a cumulative effects analysis for specific habitat restoration projects is not possible outside of its general benefit of improving overall fisheries habitat within the four tributaries.

Adequacy of HCPs

Comment 7 *The DEIS does not demonstrate that the HCPs are sufficient to protect anadromous fish in the Mid-Columbia River and that recovery will occur.*

Response 7 Text was added to FEIS Section 2.3.3.5, Adaptive Management, that includes a summary of how the projects affect overall survival for listed Upper Columbia River salmonids under Alternatives 1 and 2, and all Upper Columbia River anadromous salmonids under Alternative 3. The Quantitative Analysis Report (QAR) discussed in detail in Chapter 5 of the FEIS indicates that additional survival improvements in the Lower Columbia River, as well as improved egg-to-smolt and smolt-to-adult survival conditions, would be necessary to recover the species. However, QAR results also demonstrated an expectation that substantial survival improvements (16 to 25 percent for steelhead and 21 to 35 percent for spring-run chinook salmon) would occur as a result of meeting the performance standards in the HCPs. The analysis indicated an additional 6 to 10 percent survival benefit from tributary habitat improvements (assuming that the 2 percent mitigation level was achieved). Although the HCPs alone are unlikely to result in the recovery of either listed species, depending on the time period used in the model, the expected survival benefits would not appreciably reduce the likelihood of the survival and recovery of the species in the wild. The HCPs minimize and mitigate the impacts of the taking, to the maximum extent practicable.

Under Alternative 3, the HCP measures (including habitat improvement projects in tributary streams) would be implemented quickly with greater cooperation among the HCP signatory parties, and would additionally cover other unlisted anadromous species. The revised HCPs also establish specific methods that would be used to determine survival. The HCPs include a provision that the coordinating committees would decide on appropriate changes to these methods as assessment technology advances over the 50-year term of the agreements. The revised HCPs now require that a comprehensive analysis be prepared at the direction of the coordinating committees to (1) summarize the current status of each Plan species and (2) determine whether or not the no net impact standard is being achieved for each Plan species in 2013, and every 10 years thereafter (Section 6.9 of the Wells HCP [Progress Reports] and Section 4.9 of the Rocky Reach and Rock Island HCPs [Progress Reports]). If either of these conditions is not being met and the PUDs fail to implement agreed-upon measures to achieve or maintain the no net impact standard, NMFS may revoke the permit (after 2013 for Chelan County PUD and after 2018 for Douglas County PUD) to seek actions for achievement of the no net impact standard (see Section 2.2.1.2 of the Wells HCP [Elective Withdrawal Events Enough Already] and Section 2.1.2 of the Rocky Reach and Rock Island HCPs [Withdrawal From Agreement Enough Already]).

Some actions considered under Alternative 2 may provide similar or greater benefits than under Alternative 3. However, Alternative 2 has a much greater potential for litigation among interested parties, which would likely delay implementation of the measures, perhaps until (or even beyond) the expiration of the current project licenses. In addition, under Alternative 2 it is unlikely that unlisted species would receive the same level of protection as listed species or that tributary improvement projects would be funded.

Fisheries-Related Comments

Comment 8 *Summer and fall chinook salmon should not be considered a single species.*

Response 8 The chinook salmon status review (Myers et al. 1998) describes a variety of characteristics that support NMFS's Evolutionarily Significant Unit delineations for this species, including ecological and life-history parameters. NMFS also assessed available allozyme data for the proposed Evolutionarily Significant Unit and concluded that sufficient genetic similarities existed to include summer and fall chinook in the Upper Columbia River within a single Evolutionarily Significant Unit.

Comment 9 *What is the standard by which the status of the Evolutionarily Significant Unit is measured?*

Response 9 The standard by which the status of an Evolutionarily Significant Unit is measured is defined in law. The Endangered Species Act of 1973 as amended through the 100th Congress defines endangered as meaning "any species which is in danger of extinction throughout all or a significant portion of its range." Similarly, the Endangered Species Act defines threatened as meaning "any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range."

In making its listing determination, NMFS must consider a large body of information relating to the naturally spawned and hatchery populations within an Evolutionarily Significant Unit, such as data on population abundance, recruitment, productivity, escapement, and reproductive success (e.g., spawner-recruit or spawner-spawner survivorship, smolt production estimates, fecundity, and ocean survival rates); historical and present data on hatchery fish releases, outmigration, survivorship, returns, straying rates, replacement rates, and reproductive success in the wild; data on age structure and migration patterns of juveniles and adults; meristic, morphometric, and

genetic studies; and spatial or temporal trends in the quality and quantity of freshwater, estuarine, and marine habitats. After full consideration of this body of evidence, NMFS must make a determination, "solely on the basis of the best scientific and commercial data available," whether an Evolutionarily Significant Unit should be listed and, if so, whether it should be listed as endangered or threatened, according to the applicable statutory definitions.

Comment 10 *The geographic place and biological terms that would be used to measure progress toward recovery of the chinook salmon Evolutionarily Significant Units should be described.*

Response 10 The scientific team responsible for developing the formal recovery criteria (the Interior Columbia Technical Review Team) was established in October 2001, and is working to provide draft recommendations for recovery criteria. However, adequate technical information is currently available for this Evolutionarily Significant Unit to provide sound preliminary abundance and productivity objectives. NMFS has provided interim targets for the Interior Columbia Recovery Domain to assist subbasin and watershed recovery planning already underway in the Columbia River Basin. NMFS's interim spawner abundance targets for Upper Columbia River steelhead are 2,500 fish in the Methow, 500 fish in the Entiat, and 2,500 fish in the Wenatchee River. NMFS's interim spawner abundance targets for Upper Columbia River spring-run chinook salmon are 2,000 fish in the Methow, 500 fish in the Entiat, and 3,750 fish in the Wenatchee River. In addition to these river basins, the potential for naturally spawning aggregations of both Upper Columbia River steelhead and chinook salmon in the Okanogan River will be evaluated by the Interior Technical Recovery Team.

Comment 11 *NMFS should provide an explanation of its authority to manage units smaller than Evolutionarily Significant Units.*

Response 11 The Endangered Species Act authorizes NMFS to regulate threatened and endangered species in a number of different contexts. NMFS's authorities under the Endangered Species Act are delegated from Congress to NMFS through the Secretary of Commerce. The Secretary's Endangered Species Act listing decisions are based on the status of distinct population segments (Evolutionarily Significant Units are the equivalent of this designation for Pacific salmon and steelhead). In addition, the Endangered Species Act prohibits the take of listed individuals within an Evolutionarily Significant Unit. Section 10 of the Endangered Species Act grants NMFS the authority to allow direct take of listed individuals for research purposes and the take of individuals incidental to otherwise lawful activities. When evaluating Federal actions pursuant to Section 7 of the Endangered Species Act, NMFS considers the impact of a proposed action on the viability of populations within an Evolutionarily Significant Unit. NMFS recognizes, based on a comprehensive review and synthesis of conservation biology and salmonid literature, that a key consideration in making a jeopardy determination pursuant to Section 7 is how many and which populations are necessary for a sustainable Evolutionarily Significant Unit. In the absence of information indicating which populations are necessary for survival and recovery, NMFS assumes that each population within a given Evolutionarily Significant Unit is essential.

Off-Site Mitigation Plans

Comment 12 *A number of commenters questioned the adequacy, appropriateness, and timing of the off-site mitigation plan. Others questioned the basis for the proposed 7 percent hatchery and 2 percent habitat mix. Data were requested to document that the 2 percent Plan Species Account was adequate, how the compensation could be verified, and how compliance could be assessed. Other commenters requested the identification of specific improvement projects to allow accurate assessments of the alternatives, how the funding process would work, and whether the Plan*

Species Account funding level could be increased with a corresponding decrease in the hatchery compensation level.

Response 12 The tributary and hatchery committees would be formed immediately following permit issuance and FERC orders modifying the project license. The Tributary Conservation Plans and the Hatchery Compensation Plans would occur simultaneously and independently to ensure that both processes are implemented as quickly as possible. Priority reaches would be determined by the tributary committees, following review and evaluation of the proposed restoration measures. The results expected from these efforts would be included in the evaluations.

The approach used to translate 2 percent mitigation into habitat improvements was determined by negotiation among the participants in the development of the HCPs, which included agencies, Tribes, and the applicants. The initial process to determine the appropriate amount of mitigation for the Plan Species Account was to evaluate the types and extent of habitat improvements that would mitigate for the presumed 2 percent adult project mortality, and then proceed to determine the overall cost to conduct these types of improvements. This amount was prorated to each project based on the estimated mortality rates. Therefore, the Plan Species Account funding levels represent compensation relative to the assumed loss of adults at each of the three projects.

Because the funding levels were a negotiated amount, there were no specific evaluations conducted to assess the exact benefits that would result from the funding. In addition, different types of expenditures are expected to have different results over different time periods. For example, buying properties to hold in trust might not show immediate or even short-term benefits, but would have long-term habitat protection benefits. At the same time, allocating money to remove or replace culverts that are partial or complete barriers to fish passage could have immediate benefits associated with opening new spawning and rearing habitat.

Because of the wide range of activities that could be funded by the Plan Species Account, it is not possible to determine the exact benefits that could be expected from the account as a whole. The negotiating parties also agreed that it is not practical or efficient to spend additional funds in an attempt to quantify the results of specific improvements, which often have subtle or long-term benefits. However, the revised HCPs provide additional funding ($200,000 per project) to assess the general benefits of various types of habitat improvement measures to aid the tributary committees when determining how the Plan Species Account would be used. The mitigation proposed in the FEIS for the tributary improvements is the funding, not the actual projects. Off-site mitigation proposed for the projects includes ongoing hatchery supplementation. The projects to be funded have not yet been identified. The FEIS describes the types of projects likely to be funded but does not select the specific projects. This would be the responsibility of the tributary committees. Therefore, the 2 percent mitigation level and the adequacy of the funding are assumed to be appropriate for the purpose of the HCP process. The revised HCPs also include a Tributary Assessment Program (Sections 7.5 and 7.6 of the Wells, and Rocky Reach and Rock Island HCPs, respectively) to monitor and evaluate the relative performance of projects approved by tributary committees to ensure that the dollars allocated are utilized in an effective and efficient manner. See FEIS Section 2.3.4.8, HCP Conservation Plan and Compensation Measures.

Hatchery compensation is based on an initial estimate of 7 percent juvenile mortality through each individual hydroelectric project. This compensation level can be reduced if evaluations clearly demonstrate that project mortality is less than 7 percent. Initial hatchery production objectives are based on agreed-upon numbers that represent baseline compensation levels for the Mid-Columbia River hatchery program. The *Biological Assessment and Management Plan, Mid-*

Columbia River Hatchery Program (NMFS et al. 1998b) provides a description of the methodology and baseline numbers. In general, the initial compensation levels rely on a formula that applies a 10-year baseline of adult returns from the mid 1970s to early 1980s and historical juvenile-to-adult survival rates to the Mid-Columbia River from existing salmon and steelhead hatcheries in the region. Juvenile-to-adult survival averages encompassed the release years 1980 through 1990 for chinook salmon, 1990 through 1991 for sockeye salmon, and 1984 through 1992 for steelhead (NMFS et al. 1998b, Table 2). Hatchery evaluations will be included to provide up-to-date juvenile-to-adult survival averages. This updated survival information will be applied during the periodic review of the hatchery program to recalculate the compensation level every 10 years, beginning in 2013.

Similarly, the Plan Species Account funding level is fixed at 2 percent, and there is no intention to increase the tributary funding to replace some of the hatchery supplementation. While the additional tributary habitat work would be beneficial, these benefits would likely result in a gradual long-term improvement in fish production and survival. On the other hand, removing funds from the hatchery programs would result in immediate loss of hatchery fish, thereby affecting harvest opportunities. Recent changes to the hatchery programs are expected to minimize the impacts of hatchery fish on wild populations, and possibly increase wild populations with the use of wild broodstock programs. Hatchery programs have a greater potential for achieving short-term gains, while tributary funding provides long-term habitat improvements. Therefore, an appropriate balance is needed to recover the species and also maintain harvest opportunities on hatchery and unlisted stocks.

Both NMFS's 2000 Federal Columbia River Power System biological opinion and the All-H Recovery Plan presume that habitat improvements are not only possible but that they are essential for the recovery of listed Evolutionarily Significant Units of salmon and steelhead. Similar to the HCP, these documents specify the amount of improvement necessary (increase in life-cycle survival) and the timeline to obtain this improvement. It is the best professional judgment of NMFS and the other signatory parties that the Plan Species Account will likely compensate for 2 percent of project-related mortality.

As presently proposed in the HCPs, a comprehensive progress report would be prepared by the PUDs, at the direction of the coordinating committees, assessing the overall status of achieving no net impact in 2013 (2018 for the Wells Project), and every 10 years thereafter. To ensure that the dollars allocated to the Plan Species Account are utilized effectively and efficiently, the tributary committees would oversee tributary assessment programs. Similarly, the hatchery committees would be tasked with developing 5-year monitoring and evaluation plans for the hatchery programs to be updated every 5 years. These additions are intended to ensure that the overall effectiveness of the HCPs (including the habitat conservation and hatchery compensation programs) is periodically evaluated and that the no net impact standard is being met by 2013 (2018 for the Wells Project) and will continue to be met throughout the life of the agreement.

Specific Tributary Habitat Plan Comments

Comment 13 *Several commenters suggested that habitat restoration work be coordinated with other agencies and be consistent with meeting objectives of the Clean Water Act Section 303(d) and total maximum daily load (TMDL) development. Others questioned how the Plan Species Account should be spent, including projects to improve mainstem habitat, and how the tributary committees would function.*

Response 13 The HCPs were not developed to meet requirements of Section 303(d) of the Clean Water Act. However, the proponents would be required to comply with the provisions of the Clean Water Act regardless of which alternative is selected. The primary objective of the tributary committees will be to improve fish habitat, which may simultaneously result in water quality improvements. For example, improving damaged riparian corridors could decrease peak summer water temperatures. However, the first priority for restoration projects will be to identify projects and areas where the greatest improvements can be made in preserving, enhancing, and/or restoring fish habitat, which may not necessarily occur in areas where water bodies are impaired due to water quality issues. See FEIS Section 2.3.4.8, HCP Conservation Plan and Compensation Measures.

It is expected that the tributary committees would work closely with the local entities to coordinate habitat restoration efforts and maximize overall benefits. The mainstem Columbia River is specifically included in the Tributary Conservation Plan (see FEIS Section 2.3.4.8, HCP Conservation Plan and Compensation Measures). However, most of the habitat improvement emphasis would be directed to tributary habitat because of the wider range of restoration and protection opportunities in these tributaries and the potential to specifically benefit the listed species, as well as a greater number of other species. However, this does not suggest that mainstem habitat restoration and protection measures are inappropriate activities to be funded by the Plan Species Account. The tributary committees would determine the projects that would be funded.

Comment 14 *Some commenters requested clarification of how mitigation funding could change for Douglas County PUD and whether this was scientifically justifiable or appropriate. Others questioned how the tributary committees would select projects to fund, how other entities could participate in this process, whether tributary habitat restoration could occur under both action alternatives, and if implementation monitoring will occur.*

Response 14 As currently proposed, Douglas County PUD funding of the Plan Species Account is intended to compensate for up to 2 percent unavoidable adult and/or juvenile project mortality. The account could be reduced only if the coordinating committees determine that the adult project survival rate is equal to or greater than 98 percent and the juvenile project passage survival rate is greater than 93 percent. The signatory parties have agreed that adult survival cannot be conclusively measured at this time. Based on the best available information, the signatory parties have also agreed that Douglas County PUD has achieved the 93 percent juvenile project passage survival rate for Endangered Species Act-listed Upper Columbia River spring-run chinook salmon and steelhead. Therefore, unless new technologies or methodologies become available that would allow for the measurement of adult mortality attributable to project effects alone, Douglas County PUD's funding of the Plan Species Account would remain at full levels.

Should future studies indicate that adult survival is greater than 98 percent and juvenile project passage survival is greater than 93 percent for a given species, mitigation could decrease proportionally. For example, if future studies indicate that the adult survival rate through the Wells Project is 99 percent for steelhead, but 98 percent (assumed level) for spring-run chinook salmon, summer/fall-run chinook salmon, and sockeye salmon (as well as coho salmon should they become established as a viable population), the Plan Species Account would be reduced from a full 8/8ths contribution (2 percent for each of four Plan species) to 7/8ths contribution (2 percent for each of three species and only 1 percent for steelhead) of the Plan Species Account. If a long-term program or threshold population of coho salmon become established within the Mid-Columbia River, then coho salmon will be considered in the reduction in the Plan Species Account (e.g., 10/10ths contribution reduced to 9/10ths based upon the example of 99 percent

adult steelhead survival) (see Section 8.4.5.1 of the Wells HCP [Hatchery Compensation Plan, Production Commitments, Adjust of Hatchery Compensation – Population Dynamics for Coho]).

The current HCPs clearly state that the tributary committees shall select projects based on guidelines set forth in the HCPs (see Section 7.3.7.3 of the Wells HCP [Tributary Conservation Plan Tributary Committee, Plan Species Account Selection of Projects and Approval of Budgets] and Section 7.7.1 of the Rocky Reach and Rock Island HCPs [Tributary Conservation Plan Project Selection Geographic Area and Types of Projects]). These guidelines are further defined in the HCP supporting documents (e.g., Supporting Documents D and A of the Wells HCP). The general principles of the Tributary Conservation Plan include an assessment of all proposed restoration and habitat improvement projects, which would include identifying the status and habitat-limiting factors for the Plan species. Projects could be proposed to the committees, or the committees could also identify projects on their own. All relevant information would be reviewed and used to assess the potential benefits from each project.

The HCPs also require that, whenever feasible, the tributary committees shall (1) take into consideration and be coordinated with other conservation plans or programs when selecting projects, and (2) cost-share with other programs, seek matching funds, and piggy-back programs onto other habitat efforts. All HCP signatory parties would have the opportunity to be represented on the tributary committees. Other entities could work through these representatives to bring potential enhancement projects to the committees for consideration. While non-signatory parties to the HCP have no voting rights in the selection of projects, the tributary committees may invite other expert entities, such as land and water trusts or conservancy groups, to serve as additional, non-voting members of the committees.

Under Alternative 3, the PUDs have committed to provide a specific level of funding immediately upon issuance of the incidental take permit and FERC license articles. Over the 50-year term of the HCPs, the combined funding provided by the PUDs to the Plan Species Account would be over $46.5 million (in 1998 dollars). PUD-funded tributary habitat improvements are not included in the actions analyzed under Alternative 2 in the FEIS.

Under Alternative 3, a Tributary Assessment Program will be supported by the PUDs separate from the Plan Species Account. This program will be utilized to monitor and evaluate the relative performance of tributary enhancement projects approved by the tributary committees and directly funded by the initial contributions to the Plan Species Accounts (see FEIS Section 2.3.4.8, HCP Conservation Plan and Compensation Measures). The PUDs will develop, in coordination with and subject to approval by the tributary committees, the measurement protocols for the Tributary Assessment Program. The tributary committees would prepare a comprehensive review of the tributary program that will be provided to the respective coordinating committees for inclusion in their comprehensive review report.

Although the Tributary Assessment Program will be funded by the PUDs to determine the relative benefits of the enhancement projects, these assessments are not intended to attempt to quantify the actual benefits of the projects in terms of species status or abundance. The purpose of the Tributary Assessment Program is to verify that appropriate enhancement projects are being funded. The signatory parties agree that, even if it were technically feasible, the cost and time associated with such quantification efforts would likely exceed the costs of actually implementing habitat enhancement projects.

Specific Hatchery Plan Comments

Comment 15 *If the 7 percent hatchery compensation is reduced, how will the no net impact performance standard be met? This appears to be a contradiction of terms.*

Response 15 NMFS has agreed to issue 10-year permits for the HCP hatchery programs. Hatchery compensation levels have been set through 2013. In 2013 or at subsequent 10-year points, should new information become available indicating that these hatchery compensation levels must be reduced (due to larger than expected impact of hatchery fish on wild fish), the coordinating committees will be required to determine which actions will be continued to meet the no net impact performance standard. If a reduction in the HCP hatchery program prevents the attainment of no net impact, a party is able to withdraw from an HCP.

Comment 16 *Explain why the Quantitative Analysis Report (QAR) assumes that the supplementation program would be short-term, while the HCPs assume that the supplementation program would be long-term. The EIS should confirm that the hatchery fish are treaty resources.*

Response 16 The stated purposes of the Endangered Species Act are "to provide a means whereby the ecosystems upon which endangered species depend may be conserved, to provide a program for the conservation of such endangered species and threatened species, and to take such steps as may be appropriate to achieve (these) purposes" (see Section 2(b) of the Endangered Species Act). Over the long term, the ultimate goal of a recovery plan must be to achieve both abundance goals and the conditions necessary for natural production to be self-sustaining. The QAR was designed to provide decision makers with current assessments of the status (population trend, risk of extinction, etc.) of naturally produced Endangered Species Act-listed spring-run chinook salmon and steelhead runs returning to the Wenatchee, Entiat, and Methow River systems. The QAR was a retrospective analysis specifically designed to estimate (1) current extinction risks, (2) survival changes needed to meet alternative risk and recovery criteria, (3) sensitivity of population growth rate to survival changes in different life-history phases, and (4) potential survival changes from the HCP for the naturally produced populations. While NMFS (and the QAR results) recognizes that there is a potential role for carefully designed and monitored supplementation in recovery efforts, and that some level of hatchery production is likely to occur in the foreseeable future, assessing the status of artificially propagated fish in these basins was not the objective of the QAR.

Comment 17 *Hatcheries have not adequately compensated for the initial dam construction, and NMFS supplementation policies add additional blockages to full mitigation and compensation. Clarify how hatchery production for each Plan species will change from current production levels under each of the HCPs. The HCPs should guarantee that only wild broodstock would be used for hatchery production, and production levels should be established for coho salmon.*

Response 17 Current production levels were based on both inundation loss and about 14 percent passage loss. Hatchery production, compensating for inundation effects, is not subject to reduction at any time during the life of the HCPs. The HCPs require the PUDs to reach a combined adult and juvenile project survival level of 91 percent. The remaining 9 percent of unavoidable mortality is split between habitat improvement funding and hatchery compensation. Up to 7 percent mortality at each project would be compensated through hatchery programs. If the PUDs can demonstrate, using survival studies approved by the coordinating committees, that their passage mortality for specific species/life stage is less than 7 percent, then the hatchery production for that species may be reduced accordingly. Chelan County PUD has agreed to maintain the current production levels for ongoing hatchery programs at the 14 percent level (sockeye salmon production is at a

lower level because it is still at a feasibility level, and rearing strategies are being tested) until the first review in 2013. The programs will be reevaluated every 10 years after 2013. Funding for the existing 14 percent hatchery compensation for fish passage losses attributable to the Wells Project, provided by Douglas County PUD, would decrease to a maximum of 7 percent under the HCPs. Douglas County PUD has successfully demonstrated that passage survival for yearling chinook salmon and steelhead releases at Wells Dam is less than 7 percent and their production commitment will be adjusted accordingly. Refer to FEIS Section 4.2.3.1, Threatened and Endangered Species. The PUDs provide funding for the hatchery programs and are currently not directly involved in their operation, but could be in the future. However, because they have major responsibilities for the successful operation of the facilities, the PUDs will become co-permittees with WDFW for the operation of these facilities. The PUDs could also be the permittees for the hatcheries and their agent could operate the hatcheries under the terms and conditions of the permits issued to the PUDs.

The hatchery production levels for all Plan species (including coho salmon) will be based on average adult returns for a baseline period, a 7 percent compensation requirement, and baseline adult/smolt survival rates for existing Mid-Columbia River hatcheries. The hatchery production levels would be periodically evaluated, using these same parameters, to achieve and maintain the no net impact standard (although no more than 7 percent hatchery supplementation compensation would occur). Once this data is available for coho salmon, production levels will be set. As with the other Plan species, hatchery production levels will be reevaluated and adjusted as necessary to maintain the 7 percent compensation level.

The goals and objectives for each hatchery program will be established by the hatchery committees and may change over time depending on the success or failure of particular hatchery programs. To utilize only wild fish for hatchery broodstock may not meet the goals of the hatchery program.

Monitoring Requirements

Comment 18 *Several commenters suggested that the FEIS should explicitly identify the monitoring methods, that actions demonstrated to be sufficient to protect fish be used to measure compliance with the performance standards, and that specific operational criteria be used in lieu of basing success solely on performance standards. Others questioned the availability of methods to evaluate survival rates of all Plan species and life stages.*

Response 18 The methods currently available for monitoring compliance with the HCP (survival for all Plan species and life stages) are summarized in a supporting document to the proposed anadromous fish agreements and habitat conservation plans (see *Briefing Paper Estimating Survival of Anadromous Fish Through the Mid-Columbia PUD Hydropower Projects* by T. Cooney). NMFS readily acknowledges that, for some life-history stages of Plan species (most notably subyearling Upper Columbia River summer/fall chinook salmon and sockeye salmon), there are no technologies currently available to provide either juvenile project or juvenile dam passage survival estimates. Under Alternative 3, the coordinating committees would evaluate new technologies for use in determining the survival of Plan species through the reservoirs and dams.

Predetermining the questions that will need to be answered in the future is not appropriate because it may depend on how close the PUDs are to achieving the performance standards. For example, if the survival rates at a project were substantially lower than the performance standard, specific passage route assessments might be appropriate to determine where the greatest impacts are occurring. However, if the survival rates were close to the performance standard, then more

accurate estimates of total project survival would be suitable. Each of these assessments would use different methodologies. The coordinating committees would be responsible for determining what studies should be conducted at each of the projects.

Defining specific actions or measures (e.g., specific spill programs) to protect fish, in lieu of performance standards, has typically been used in the basin to provide interim levels of protection for anadromous fish. Examples of this approach include the Wells Interim Protection Plan biological opinion (expired), Rock Island Settlement Agreement, and Rocky Reach bypass biological opinion that the PUDs are operating under (e.g., specific spill programs). This general approach is now represented in the FEIS by Alternative 2. A similar approach is likely to be implemented under both action alternatives. For Alternative 3, based on available information, initial operations (e.g., spill levels) have been established that might achieve the pertinent juvenile survival standards for each Plan species. If Phase I studies indicate that performance standards are not being met, the coordinating committees would adjust the protection measures at the projects to meet appropriate survival levels (for example, increase spill levels to meet the juvenile dam survival standard for sockeye salmon). Therefore, both processes are very similar, with the primary differences being how and when the decisions are made. Under Alternative 3, the measures would be implemented immediately and would benefit all Plan species. Under Alternative 2, the measures would likely not be implemented until Endangered Species Act consultations were completed and FERC issued license orders (potentially after all appeal processes have been exhausted) for each project, and the non-listed species would likely not receive the same level of protection as those that are listed. Should litigation ensue, these measures may not be fully implemented for years or even decades.

The HCPs would establish coordinating committees to select and guide the appropriate monitoring and evaluation procedures. The committees are expected to use the best available data to determine if the HCP objectives are being met. However, even under optimal conditions, a number of assumptions are required to estimate project impacts. Due to the complexity of the issues involved, there are frequent disagreements over these assumptions or the results of the data analysis. The HCPs include committees and a dispute resolution process to facilitate appropriate and timely decisions on the adequacy of the data or the need for additional evaluations. In addition, the coordinating committees have the ability to select an independent third party for the purpose of providing an independent scientific review of any disputed survival study results and/or reports. Survival studies would be conducted for all Plan species, except where no appropriate methodology exists.

The provisions of the Endangered Species Act require the use of the best available scientific data. The monitoring and evaluation methods currently being used to evaluate survival at the projects provide the best available data. The same methods of evaluation would likely be used for both action alternatives, and are consistent with monitoring standards throughout the basin. In the future, should newly developed methods be found that provide more accurate results, these new methods would be implemented at the discretion of the coordinating committees during the reevaluation every 10 years (e.g., Rocky Reach HCP Section 5.3.3 [Phase III Standard Achieved]). Due to the considerable expense of conducting survival studies, the limited availability of test fish (particularly for depressed stocks), and the limitations of the assessment techniques, it is not feasible to acquire survival data throughout the entire migration period of all species passing the project. Therefore, it is sometimes necessary to use data from surrogate species or life stages to estimate survival for those species or life stages that cannot be directly evaluated. Although this might not be the ideal monitoring option, this method may provide the only information available.

HCP-Related Questions

Comment 19 *Several commenters requested a better description of the HCP negotiation process, including the number of outstanding issues that have not been satisfactorily resolved for all the parties. They questioned the appropriateness of proceeding with the NEPA review process until these issues are resolved. Some suggested reopener clauses be included in the HCPs to allow some intervention if the species were not recovering.*

Response 19 The original signatory parties began intensive negotiations to resolve outstanding issues raised in comments on the DEIS in September 2001. The outstanding issues were resolved to the satisfaction of NMFS, USFWS, WDFW, the PUDs, and the Colville Tribe, who signed the HCPs pending completion of the regulatory review process. These clarifications have been added to the HCPs for each of the three projects and added to Chapter 2 of the FEIS.

The two basic requirements of NEPA (the premise for preparation of this FEIS) are that (1) the agency considers significant aspects of the *environmental* impacts of a proposed action and (2) the agency informs the public that it has considered *environmental* concerns in its decision-making process. NMFS has encouraged all HCP applicants to invite and include other Federal and State agencies who can utilize their existing authorities, expertise, or lands in support of the HCP development and implementation process. Furthermore, NMFS considers whether the proposed plans might affect Tribal rights to trust and treaty resources. After careful consideration of Tribal concerns, NMFS will clearly state the rationale for the recommended final decision and explain how the decision relates to the government's trust responsibilities. In light of this obligation, it is important that during the planning process, NMFS identifies and evaluates the anticipated effects of a proposed HCP upon Indian treaty and trust resources as provided in the EIS.

In the FEIS, NMFS has indicated that the issuance of Incidental Take (Section 10) permits in support of the HCPs is the agency's preferred alternative. This FEIS constitutes an environmental review of the proposed project. The preferred alternative would then be subject to review in the preparation of a biological opinion. The biological opinion could include additional stipulations than those currently in the HCPs. Therefore, the FEIS does not presume that the HCPs are final, official, and suitable for implementation. However, if NMFS issues a permit with terms and conditions in addition to or different from those set forth in the HCPs, any party, including the PUDs, may withdraw from the agreements within 60 days of the effective date. The FEIS review process fulfills NMFS's NEPA compliance obligations as required for HCPs. Using the NEPA FEIS and biological opinion that would be prepared for the HCP, NMFS will evaluate whether the HCPs meet the requirements of Section 10 of the Endangered Species Act. Although NMFS would prefer that all parties involved in the HCP negotiation process sign the HCPs and participate in HCP implementation through the HCP committees, there is no mandated requirement that all parties sign the HCPs.

FERC has no mandate under the Endangered Species Act other than to consult with NMFS and USFWS (the Services) when their actions have the potential to affect listed species. Therefore, FERC cannot mandate reopener clauses in the HCPs or the incidental take permits. FERC can and has included reopener clauses in their licenses that allow opportunities to reconsider fish and other natural resource issues. However, only a non-signatory party could initiate (at relicensing) the reopener process for the Plan species under Alternative 3. Signing parties enforce compliance with the HCPs, or they may exercise their rights to withdraw from the HCPs. It is also important to note that even the signatory parties can petition FERC during the relicensing process to include

protection provisions for non-Plan species, which are not included in the HCP process. This would include fish species, such as lamprey and bull trout, that could be affected by the projects.

As stated in FEIS Section 2.6.2.3, Alternative 3, as a signatory party to the HCPs, NMFS would not institute any additional action for the Plan species beyond the HCP performance standards under provision of the Endangered Species Act. However, the HCPs have termination provisions (see FEIS Section 2.3.4.2, HCP Term) that allow NMFS to withdraw after 15 years (20 years for the Wells Project) if (1) the no net impact standard has not been achieved or has been achieved but has not been maintained, or (2) the Plan species are not rebuilding and the project is a significant factor in the failure to rebuild. In addition, NMFS may suspend or revoke the incidental take permit in the event that NMFS and the PUD cannot reach agreement on specific measures to remedy the PUD's failure to achieve or maintain the no net impact standard or if the PUD fails to promptly implement measures that are applicable to the PUD (see Section 2.2.1.2 of the Wells HCP [Termination, Elective Withdrawal Events, Enough Already]).

The NMFS "All H" initiative identifies harvest, hatcheries, habitat, and hydropower as the primary means for addressing species recovery in the basin. The HCPs address issues primarily related to hydropower, although there are some habitat and hatchery components in the plans. However, they do not affect NMFS's ability to address recovery through these other issues or processes that have also contributed to the decline of the species.

Effects of HCPs on Other Plans or Processes

Comment 20 *Several commenters requested clarification of how NMFS can satisfy their treaty trust responsibilities to provide Tribal harvest under the proposed HCPs. There were concerns over how NMFS could provide further protection for the listed species if the HCPs do not lead to recovery. Other concerns were that NMFS not use the HCPs as a defense in any non-HCP-related litigation between NMFS and the Tribes, or reduce the existing Tribal influence on management decisions through the Mid-Columbia Coordinating Committee.*

Response 20 These concerns are addressed in FEIS Section 4.12.17, Legislation Pertinent to Tribal Governments. Formal consultation between NMFS and the Tribes on a government-to-government basis will include discussions of these issues, and would occur prior to issuance of a record of decision (ROD) or a final biological opinion on the HCPs. NMFS and USFWS (the Services) can withdraw from the HCPs and revoke the permit even if the no net impact standard has been met, if the Plan species are not rebuilding and the project(s) are a significant factor in the failure to rebuild. The revised HCPs specify that no net impact standards must be achieved by 2013 or 2018 for the Wells Project (see Section 2.2.1.2 of the Wells HCP [Termination, Elective Withdrawal Events, Enough Already]). This allows adequate time to assess the project operation tools used to improve fish survival conditions and to evaluate these improvements over several fish population life cycles. These time periods include 5 years for the PUDs to reach the performance standards, 3 years of evaluation of the juvenile survival metrics (juvenile project survival or juvenile dam passage survival), and about two adult return cycles.

The HCPs by themselves are not recovery plans. In addition to the fish passage conditions at the Mid-Columbia River projects, species recovery is dependent on a number of other factors, including improvements in (1) fish survival conditions in the Lower Columbia River, (2) habitat, (3) hatchery programs, and (4) estuary and ocean survival rates. Fish passage survival rates in the lower river have improved substantially in recent years. Habitat restoration planning and implementation have also intensified, the hatchery programs have improved, and the efforts to reduce avian predation levels in the Columbia River estuary also have the potential to

substantially improve overall recovery. In addition to these improvements within the basin, ocean rearing conditions appear to be shifting to a more favorable status. These improvements will not result in instantaneous species recovery, and will require a number of years to fully evaluate and quantify the benefits. The overall fish survival conditions in the Columbia River Basin appear to be improving and it is unlikely that this trend would be reversed or substantially affected by the 15- or 20-year time period to fully evaluate survival improvements at the PUD projects.

The HCPs continue to include a provision with respect to Indian Tribal treaty or reserved rights claims. Section 12.11 [Indian Tribal Treaty or Reserved Rights] of the HCPs states that "nothing in this Agreement is intended to nor shall it in any way abridge, limit, diminish, abrogate, adjudicate, or resolve any Indian right reserved or protected in any treaty, executive order, statute or court decree." In addition, the HCPs have been revised to state that "this Agreement will not be utilized against another Party in any manner whatsoever in any legal proceeding other than a legal proceeding to enforce or interpret this agreement" (see Section 12.11 [Indian Tribal Treaty or Reserved Rights] of the HCPs).

The outcome of FERC's final order approving the HCPs and incorporating them into the project licenses is as follows:

- For Wells: replacing the Wells Settlement Agreement with the HCP, replacing the Interim Protection Plan biological opinion (now expired) with the HCP, and replacing the Settlement Agreement's Coordinating Committee with the HCP committees.

- For Rocky Reach: settling the Rocky Reach portion of the pending Mid-Columbia Proceeding at FERC, replacing the Mid-Columbia Coordinating Committee with the HCP committees, and replacing the bypass order and biological opinion with the HCP.

- For Rock Island: replacing the Rock Island Settlement Agreement with the HCP, and replacing the Settlement Agreement's coordinating committee with the HCP committees.

At this point, the Yakama and Umatilla Tribes have not signed the HCPs, and therefore are not entitled to participate directly on the HCP committees, which are limited to signatory parties. While there remains some potential for non-signatory parties who participated in HCP development to participate in the committees as non-voting members, the influence of these non-voting Tribal parties would be exercised through coordination and possibly government-to-government consultation with Federal parties who participate on the HCP committees.

It should be noted that under Alternative 3, should the Permit species fail to rebuild and the projects be determined to be a significant factor in the failure to rebuild, NMFS could withdraw from the HCPs even though the PUDs are meeting the no net impact standard. This provision of the HCPs is consistent with the requirement in the Endangered Species Act that Section 10 permits be issued only if NMFS finds that any incidental taking of species "will not appreciably reduce the likelihood of survival and recovery of the species in the wild." The HCPs also describe the hatchery mitigation that will occur through 2013, and the process for modifying these mitigation levels thereafter (see Section 8 [Hatchery Compensation Plan] of the HCPs). Under Alternative 2, NMFS would continue to issue permits to the State of Washington for the continued operation of mitigation hatcheries. Both action alternatives would require periodic evaluations to ensure that hatchery mitigation is provided in a manner that minimizes adverse impacts to Endangered Species Act-listed salmon and steelhead. Thus, with respect to the

provision of harvestable fish populations through the term of the HCPs (50 years), there would likely be minimal difference between Alternatives 2 and 3.

Uncertainties Associated with the HCPs

Comment 21 *Several commenters expressed concerns that the risks and uncertainties associated with the HCPs are disproportionately balanced on the resource (salmon and steelhead). Some were concerned over the dispute resolution process in the HCPs, and how it decreases NMFS's regulatory authority by requiring them to provide a preponderance of evidence in a dispute over gaps in the information concerning fish passage and survival. Others suggested that, because the listed species are best suited for the existing survival evaluation methods, Section 7 consultation would provide the same protection level as the HCPs for listed and unlisted species, without having to commit to a 50-year agreement.*

Response 21 The HCPs establish specific survival rate standards for all the Plan species, thereby providing the same level of protection to unlisted species as to listed species. Thus, higher standards are established for the unlisted species than might otherwise be required. The HCP survival standards are also different from the measures required in the biological opinion for the Federal system (NMFS 2000a), which sets operational limits for the projects. These operational measures establish limits on factors such as river flow targets, fish passage efficiency levels, and turbine efficiency operating levels. The operational measures assume that survival benefits will occur, while the HCPs set specific survival standards that must be met by 2013 (2018 for the Wells Project).

The intent of the HCPs is to provide no net impact survival conditions for both listed and unlisted anadromous species through the use of on-site passage survival improvements, off-site production of hatchery fish, and off-site enhancement of tributary habitat. The signatory parties to the HCPs would participate on the coordinating committees and participate in the selection of appropriate monitoring methods for each of the Plan species. However, by signing the HCPs, the signatory parties would forfeit or substantially reduce their rights or authorities to gain additional protection measures for the listed or unlisted Plan species through other laws and statutes, without first withdrawing from the agreements. Under Alternative 3, the PUDs are required to show that the performance standards are met not only at the end of Phases I and II, but also periodically during Phase III. Therefore, as survival estimation techniques are developed over the 50-year HCP terms, these techniques would be incorporated into the monitoring process to demonstrate continued compliance with the performance standards.

The revised HCPs specify the methodologies by which the survival standards shall be measured. The HCP signatory parties have agreed that point estimates of survival measurements from 3 years of valid studies shall be averaged (arithmetic mean), and that this average will be used to compare against the pertinent survival standard. A valid study is one in which the study design, implementation, and criteria are determined to be acceptable by the appropriate coordinating committee, and one in which the study occurs during representative flow conditions and normal project operating conditions consistent with the approved study design (see Section 4.1.4 of the Wells HCP [Passage Survival Plan, Methodologies] and Section 5.2.3 of the Rocky Reach and Rock Island HCPs [Implementation of the Survival Standards, Methodologies]). In addition, NMFS developed a briefing paper that summarizes the strengths and weaknesses of existing technologies for estimating survival standards. This paper was developed to assist the coordinating committees in selecting study methodologies for each of the Plan species (see Supporting Document D of the Rocky Reach and Rock Island HCPs and Supporting Document C of the Wells HCP). The use of a simple average for determining compliance with the survival

standards, as opposed to a statistical mean with confidence intervals, eliminates any possibility of a party claiming that a standard had been met because it did not differ significantly from the survival study estimate.

The signatory parties agree that the HCPs are not intended to create jurisdiction in any court. Any dispute arising in the tributary or hatchery committees would be sent to the appropriate coordinating committee for resolution. Any unresolved disputes within the coordinating committees would be sent to a policy committee for resolution. If no resolution can be reached at the policy committee, then any party may pursue any other right that they might otherwise have. Thus, as revised, the HCP dispute resolution process itself is non-binding and does not significantly reduce NMFS's regulatory authority.

HCP Phases and Testing Criteria

Comment 22 *Several commenters expressed concerns as to whether all five Plan species could be evaluated during a 3-year period, and the potential impacts on a species in the first 5 years of the HCPs when the PUDs have essentially full authority to determine what measures are implemented. Others questioned what the impacts would be if the HCP standards are not met in the 5-year period, or if they are never met. There were requests for additional information concerning the process for moving out of Phase I, and how the different phases would be implemented in the HCPs. There were some concerns that NMFS's Federal responsibility and ability to ensure the survival and utilization of endangered trust resources are effectively and impermissibly transferred to non-Federal parties in the HCPs because the projects are only subject to periodic reviews and NMFS will not be able to require any additional actions.*

Response 22 The signatory parties modified the HCPs to resolve several issues brought to light from DEIS comments. The coordinating committees now have the authority to (1) establish the protocols and methodologies to determine whether or not the survival standards are being achieved for each Plan species, (2) determine the most appropriate standard to be measured for each Plan species (see Figure 2-4 of the FEIS), (3) approve all studies prior to implementation, and (4) provide input to the PUD's choice of measures during Phase I. Thus, while the PUDs maintain the final say over what suite of structural and operational measures will be tested in Phase I of the HCPs, the coordinating committees will determine which survival standard can be appropriately evaluated for each Plan species and the committees have final approval of study plans prior to implementation. The committee decisions will be guided by a white paper, developed by NMFS and incorporated into the HCPs, when making determinations. In addition, NMFS is represented in the coordinating committees, which require a unanimous vote of meeting representatives to make determination decisions. Therefore, the HCPs have been modified to ensure that NMFS's authority is not transferred to a non-Federal entity, and that additional review (and withdrawal/termination) provisions are included. In the event that Phase I studies indicate that a pertinent survival standard is not being met for any or all Plan species, the coordinating committees are authorized to periodically adjust the measures to address survival deficiencies (Phase II). Additional information is provided in FEIS Section 4.2.3.1, Threatened and Endangered Species pertaining to impacts to species within Phase I of HCP implementation.

The required HCP Phase I survival studies should be completed by 2002 at the Wells Project, by 2004 at the Rock Island Project, and by 2006 at the Rocky Reach Project, unless the coordinating committees determine that another year of study is required. The later dates for the Chelan County PUD projects were included in the HCPs for two reasons. First, Chelan County PUD is currently constructing a juvenile fish bypass facility at the Rocky Reach Project. This facility should become operational by April 1, 2003. After 1 year of shake-down studies to assess the

facility and help fine-tune operations, Phase I survival studies would be conducted between 2004 and 2006. Second, Chelan County PUD is coordinating with consultants, NMFS Science Center, and USGS Biological Research Division to design and develop an acoustic tag survival assessment methodology. If successful, this technology would allow for the measurement of the 95 percent dam passage survival standard at the projects, and would produce a better estimate of this survival standard than would a calculation (see Survival Standard Decision Matrix [Figure 2-4 of the FEIS]).

A Survival Standard Decision Matrix (see Figure 2-4 of the FEIS) was incorporated into the HCP to clarify the priority of Phase I survival standard measurements: (1) combined adult and juvenile project survival, (2) juvenile project survival, (3) juvenile dam passage survival, and (4) calculated juvenile dam passage survival. The matrix, along with the accompanying text, more clearly indicates the phase determination that would occur after Phase I studies have been completed (see Section 4.1 of the Wells HCP [Passage Survival Plan, Survival Standards] and Sections 5.1 and 5.2 of the Rocky Reach and Rock Island HCPs [Passage Survival Plan, Survival Standards Decision Matrix and Implementation of the Survival Standards]). This information is summarized in FEIS Section 2.3.4.4, HCP Performance Standards.

The HCPs now explicitly state that the no net impact standard will be met no later than 2013 and that representative species will be chosen by the coordinating committees for additional survival studies in each 10-year period thereafter to ensure that the no net impact standard continues to be met. In the event that the standard is not being met and the PUDs fail to implement agreed-upon measures to achieve or maintain the no net impact standard, or if the Plan species are not rebuilding populations, NMFS may revoke the permit (after 2013 for Chelan County PUD and after 2018 for Douglas County PUD) to seek actions to recover the species (see Section 2.2.1.2 of the Wells HCP [Termination, Elective Withdrawal Events, Enough Already] and Section 2.1.2 of the Rocky Reach and Rock Island HCPs [Withdrawal From Agreement, Enough Already).

Regardless of the alternative selected, the survival rates of listed and/or unlisted species are expected to improve over time as the PUDs attempt to meet the performance standards or other criteria established through the Endangered Species Act consultation process. If the performance standards are not met under Alternative 3, the PUDs will be required to apply additional species-specific protective measures (also referred to as tools in the HCP and FEIS) in an effort to meet the performance standards for all Plan species. If the performance standards cannot be met, and the permit is revoked, the procedures for improving survival rates would be similar to those described in Alternative 2.

Under Alternative 3, after Phase I testing is complete, the coordinating committees are authorized to adjust measures to increase survival for those Plan species that received a Phase II designation. Should a Plan species receive a Phase III (Provisional Review) designation, the PUDs would have a one-time 5-year period to implement additional measures or conduct additional survival studies to more accurately determine whether the pertinent survival standard is being achieved. Should a Plan species receive a Phase III (Additional Juvenile Studies) designation and the coordinating committees approve the use of a new survival methodology, the PUD would have 5 years to conduct the appropriate evaluations, after which the coordinating committees would make a new phase determination for that species, which might require additional measures to be implemented. Thus, both Alternatives 2 and 3 could require additional measures if the available information indicates that existing measures do not adequately meet survival standards. The primary difference is that Alternative 3 will likely generate more survival information in a shorter amount of time and for more species than would Alternative 2 because more species will be evaluated. In addition, because Alternative 3 requires survival standards to be achieved for all Plan species,

rather than just Endangered Species Act-listed species, listed species may actually receive higher protection than would otherwise occur under Alternative 2. For example, if higher spill levels are required to meet the juvenile project survival standard for sockeye salmon, spring-run chinook salmon and steelhead will likely enjoy higher survival than they otherwise may have received. For Alternative 2, refer to FEIS Section 2.3.3, Alternative 2. For Alternative 3, refer to Sections 2.3.4.5, HCP Phases, and 2.3.4.8, HCP Conservation Plan and Compensation Measures.

Compliance with Federal, State, and Local Laws

Comment 23 *Several commenters requested clarification of how the HCPs would satisfy requirements of the Federal Power Act, Clean Water Act, and other Federal and State laws to meet water quality standards and fish protection and Tribal treaty trust responsibilities.*

Response 23 The HCPs were developed as comprehensive settlements between those that sign the Wells, Rocky Reach, and Rock Island HCPs to protect five species of anadromous salmonids under the Endangered Species Act, Federal Power Act, Fish and Wildlife Coordination Act, Pacific Northwest Electric Power Planning and Conservation Act, Essential Fish Habitat provisions of the Magnuson-Stevens Fishery Conservation and Management Act, and Title 77 RCW.

Under Section 10 of the Endangered Species Act, the HCPs would result in incidental take permit applications for each project. If NMFS concludes that the HCPs satisfy the requirements of Section 10 of the Endangered Species Act, NMFS would issue the requested permits. While making this decision, NMFS would also consider the HCPs' effects on habitat under the Magnuson-Stevens Fishery Conservation and Management Act.

The HCPs also constitute the terms, conditions, and recommendations for Plan species under Sections 10(a), 10(j), and 18 of the Federal Power Act and the Fish and Wildlife Coordination Act of the parties that sign, and satisfy any obligations the projects have in relation to game fish under Title 77 of the Revised Code of Washington.

While the HCPs do not expressly settle issues surrounding the Clean Water Act, the parties that sign agree to work cooperatively to address water quality issues. The HCPs do not abridge, limit, diminish, abrogate, adjudicate, or resolve any Indian right reserved or protected in any treaty, executive order, statute, or court decree. Nevertheless, NMFS would consult with the Tribes before taking action on the pending incidental take permit applications.

Refer to FEIS Section 3.3.2, Water Quality for a discussion of how the projects currently meet Clean Water Act requirements and FEIS Section 4.3.2, Water Quality for a discussion of the likelihood that these requirements would be met under the different alternatives. These responsibilities would be considered by the PUDs and the coordinating committees when implementing or recommending specific measures to meet the requirements outlined in the HCPs or Section 7 consultation.

See FEIS Sections 2.6.6.2, Alternative 2 and Section 2.6.6.3, Alternative 3 that discuss the application of the protection provisions of other laws and statutes for the two alternatives. These other laws and statutes would be available to non-signatory parties to the HCPs to seek additional protection for Mid-Columbia River fish stocks.

The HCPs do not mandate or guarantee compliance with laws that establish or mandate regulatory responsibilities to other non-signatory parties. Nor do they limit the discretion of or alter or affect the statutory and other legal rights of these non-signatory parties, including any

rights to legal remedies, or their authorities, responsibilities, or obligations under relevant laws or Federal processes. This includes their responsibilities and legal rights under the Endangered Species Act (outside of the Plan species), Magnuson-Stevens Fishery Conservation Act, Clean Water Act, Federal Power Act, Fish and Wildlife Coordination Act, Pacific Northwest Power Planning and Coordination Act, FERC relicensing process, Tribal treaty rights, Federal trust responsibility, and others. However, NMFS is the only agency with mandatory conditioning authority for the listed anadromous fish species under the Federal Power Act and the Endangered Species Act. Under both action alternatives, NMFS would issue a biological opinion that would identify the recovery measures and approaches to be used for species recovery. See FEIS Sections 1.1, Introduction and Section 4.12, Relationship to Laws and Policies. The action alternatives would conform to pertinent legislation of these laws regarding fish protection measures for the two listed Plan species relevant to the Endangered Species Act and the Magnuson-Stevens Fishery Conservation and Management Act.

Under Alternative 3, the HCPs would supercede the existing FERC license articles for Wells and Rock Island and settle the Mid-Columbia Proceedings for Rocky Reach. NMFS and the other signatory parties expect that FERC would amend the existing licenses to include the provisions outlined in the HCPs and/or the incidental take permit into each of the projects' FERC licenses. The fish protection measures and methodologies proposed under the HCPs would represent long-term settlement agreements under the Federal Power Act and other laws referenced above. As such, they are consistent with provisions in those statutes. However, at relicensing, the HCPs are not automatically reinstated, but the signatory parties to the HCPs have agreed to be supportive of the HCPs during relicensing. FERC is not obligated to incorporate all of the provisions in the HCPs, and can also specify additional mitigation requirements. However, if FERC does not incorporate the HCPs in their entirety or adds terms and conditions that are inconsistent with the HCPs, the parties are allowed to withdraw from the HCPs.

Drawdown, Dam Removal, Non-Power Operations, and Normative River Conditions

Comment 24 *Several commenters suggested that reservoir drawdown options were misrepresented in the DEIS as an available option under Alternative 3. In addition, drawdown, dam removal, and non-power operations should be independent alternatives in the FEIS. Some indicated that NMFS can require a dam removal alternative to be considered in the EIS, and they should also require an alternative that requires additional protection over that proposed under Alternative 3. Others sought clarification of why drawdown or dam removal could only be considered under relicensing if NMFS believed that these options were necessary to meet recovery standards, and why would there be a delay in the implementation of these measures?*

Response 24 Drawdown could be an option under both action alternatives, and the FEIS revisions clarify this point. Note that though the HCPs limit the use of drawdown options to protect the Plan species, the HCPs provide specific language under Section 2.2.1.2 of the Wells HCP Termination, Elective Withdrawal Events Enough Already and Section 2.1.2 of the Rocky Reach and Rock Island HCPs , Withdrawal From Agreement, Enough Already that allows NMFS and USFWS (the Services) to seek drawdown, dam removal, or non-power operations (with or without terminating the agreements or the permits) if the survival standards are not met after 15 years (20 years for the Wells Project). Drawdown can also occur under Alternative 3 by mutual agreement between the parties without requiring the termination of the agreements or the permits. However, the Services can also withdraw from the agreements to pursue drawdown or dam removal options. Although the HCP signatories agree to not advocate drawdown or dam removal during relicensing, non-signatory parties could still pursue these options, and FERC could order

drawdown and dam removal as an option. The environmental effects of drawdown are discussed in Chapter 4 of the FEIS for each resource.

The Services can withdraw from the HCP(s) and revoke the permit(s) (and therefore seek drawdown) even if the no net impact standard has been met, if the Plan species are not rebuilding and the project(s) are a significant factor in the failure to rebuild. This could happen even if the PUDs complied with all of the provisions of the HCP(s). If the Services withdraw from the HCP(s), then Section 7 consultation would be required before FERC takes action on proposals to replace the HCPs. Drawdown could also be an alternative during that consultation process. Therefore, drawdown (or dam removal or non-power operations) is a viable option under both action alternatives. In either case, the Services would need to demonstrate that the project(s) are a significant factor in both the decline and the failure of the species to recover.

Under the HCPs, if the PUDs are unable to achieve the performance standards (Phase II), the coordinating committees will jointly decide what measures must be taken to achieve the pertinent standard. Under Alternative 2, the PUDs would likely be required to meet Section 7 survival standards for Endangered Species Act-listed species only (spring-run chinook salmon and steelhead). The protection for sockeye, coho, and subyearling chinook salmon would likely be less under Alternative 2 because no Section 7 survival standards could be enforced. Any additional protection measures for unlisted species would likely only occur during relicensing or license reopener proceedings.

Under all alternatives, however, drawdown or other non-power options would not be pursued until all other reasonable options to recover the species were exhausted. Therefore, although the HCPs might initially commit the authority of the Services, the agency maintains its ability to pursue dam removal or drawdown over the long term.

The effects of drawdown have been analyzed in the FEIS, and these effects would be similar to a separate drawdown alternative as an additional action alternative. Because these options are available under both action alternatives, it would be redundant to also consider drawdown as an independent alternative because the environmental effects are already displayed in the analysis. Dam removal could be considered under project relicensing by FERC as described in FEIS Section 2.5.1, Dam Removal.

The Quantitative Analysis Report (QAR) analysis indicates that dam removal would not recover the species under all circumstances. Other additional factors (downstream hydroelectric projects, habitat, harvest, and hatcheries) are contributing to species impacts and are affecting the recovery process. Another factor that is suspected of being a substantial influence is ocean and climatic conditions. This is indicated by the near record returns of spring-run chinook salmon and steelhead to the basin in recent years, despite the fact that fish passage conditions have not substantially changed in this same period of time. Therefore, fish passage improvements in the overall hydro system in recent years are unlikely to fully account for these substantial increases in adult returns. Although the majority of these fish are of hatchery origin, they were subject to the same general fish passage conditions as wild fish as they migrated through the Columbia River system. Because there is no clear evidence to suggest that dam removal would substantially improve the recovery process or increase harvestable surpluses, dam removal or decommissioning is unlikely to occur in a timely manner. Even under the relicensing process, drawdown or other non-power options would likely not be exercised until all other reasonable options to recover the species were exhausted. Legal challenges to such an order would likely delay the implementation of these options indefinitely.

Use of Normative River Conditions as Baseline

Comment 25 *Normative river conditions are essential to long-term salmonid survival. Commenters suggested that the EIS should consider normative river and multi-species restoration, the risk of HCP assumptions being incorrect, the potential for the alternatives impacting other species or life stages, and the feasibility of introducing coho salmon. Others suggested that the EIS is speculative regarding the benefits that could occur from minimum operating pools, which haven't been studied at the Mid-Columbia River projects.*

Response 25 According to the *Habitat Conservation Planning and Incidental Take Permit Processing Handbook* (USFWS and NMFS 1996), the purpose of the habitat conservation planning process, and subsequent issuance of an incidental take permit, is to "authorize the incidental take of threatened or endangered species, not to authorize the underlying activities that result in the take." In this instance, the authorization for the activities that result in the take (continued operations of the project) is the responsibility of FERC during the relicensing process. FERC is not required to use normative river conditions as the baseline conditions for their evaluations. Refer to 55 Fed. Reg. 4:8-9 [Jan. 2, 1990]; FERC Stats. and Regs., Regulations Preambles 1986-1990, paragraph 30,869 at p. 31,613 (1989). Therefore, it is not appropriate to use normative river conditions as baseline conditions for the evaluation of the proposed HCPs.

The Mid-Columbia River projects are run-of-the-river facilities, which have limited capacity to change Columbia River flows. The large upstream storage projects are operated to capture spring run-off flows and release the water during otherwise lower flow periods. Therefore, these upstream projects control the ability to reestablish normative river flows in the basin. The normative river flow option available for the Mid-Columbia River projects is simply a drawdown option. (See response to Comment #24 for a discussion of drawdown options and Comment #74 for additional discussion on normative flows.)

Alternative 3 is consistent with the multi-species restoration approach because this alternative includes both listed and unlisted species as Plan species. This provides equal protection requirements for the Plan species (including coho salmon) through the establishment of consistent performance standards. Measures described in Alternative 2 would likely only provide additional protection for the listed species through the Section 7 consultation process (which could coincidentally provide a benefit to some unlisted species as well). Additional protective measures for unlisted species could only be obtained through other processes, such as FERC relicensing. Because of these differences, Alternative 3 is less likely to select for certain species or life stages than Alternative 2.

Although an analysis of the risks that the HCP assumptions are not correct has not been specifically assessed, the primary basis of the HCPs is to establish an adaptive management framework for protecting all of the Plan species. The adaptive management process is an iterative approach that relies on periodic assessments to determine if the existing conditions are improving survival and leading to the recovery of the species. This approach allows for modification to be made to the program to help ensure that adequate protection is provided to the Plan species.

In addition, the revised HCPs provide specific options for NMFS to withdraw from the HCPs if the species are not recovering and the projects are a significant factor in the failure to rebuild, even if the HCPs' no net impact standard has been achieved. This provides adequate protection against the HCP assumptions being wrong.

The Quantitative Analysis Report (QAR) analyzed Upper Columbia River spring-run chinook salmon and steelhead data from three periods: 1960 to 1994, 1970 to 1994, and 1980 to 1994. Because the shorter of these series resulted in the most pessimistic population trends, NMFS focused on this data series as the most conservative estimate of survival improvements that would be necessary to meet extinction risk and recovery metrics. The longer time series require less survival improvement to meet these same metrics. In the event that the HCP standards are not met (i.e., survival is lower than expected) for listed species during Phase I studies or at the 2013 check-in evaluations, extinction risks would increase and the likelihood of recovery would decrease compared to the estimates currently provided by the QAR. The extent of this impact would be dependent upon the size of the discrepancy and the length of time the discrepancy existed, and cannot be assessed at this time. However, the revisions to the HCPs that provide periodic evaluations (on a 10-year basis) are expected to minimize the risks of inadequate HCP standards or of the HCP assumptions being incorrect.

Compared to Alternative 1, actions implemented through Alternative 3 would immediately increase the survival rates of all Plan species. The same is true for Alternative 2. However, because implementation of measures described in Alternative 2 would likely occur only after litigation and appeals processes are exhausted, delays measured in terms of years or decades would be likely before the measures were fully implemented. It is also likely that these measures would be fully implemented to protect listed but not unlisted species or that only partial implementation would be provided for unlisted species (decreased amount or duration of spill programs, for example).

The primary benefit of the minimum operating pool concept is to reduce the cross-sectional area of the river, which would result in an increase in water velocity, and potentially increase juvenile migration speed. The assumption associated with this concept is that increased migration speed results in an increase in survival rate because the migrants would have less exposure time to predators or other river conditions (e.g., temperature) that have been shown to impact survival. However, the theory of increased migration speed with increased water velocities has not been consistently observed for the various anadromous species in the Columbia River Basin. Berggren and Filardo (1993) found a weak or non-existent relationship between migration travel time and river flow for yearling chinook salmon in the Mid-Columbia River reach. Giorgi et al. (1997) found that flow was the best single predictor of travel time for Mid-Columbia River sockeye salmon and steelhead, but not for yearling chinook salmon.

Giorgi et al. (2002) found little evidence supporting a flow survival relationship, based on PIT-tag evaluations conducted between 1993 and 2000. However, low flow conditions in 2001 resulted in a dramatic reduction in juvenile steelhead survival migrating through the Snake and Columbia Rivers (from a typical 90 percent per project survival rate to about a 63 percent survival rate per project). The slow migration speed observed in 2001 and the increased water temperatures during the migration period are considered the causative factors for the dramatic decrease in survival and increased residualization of steelhead.

In addition to inconsistencies in the flow to travel time relationships for different species and between years, there are inconsistencies in the relationship between flow (velocity) and survival. Given a constant flow, drawdown to minimum operating pool would increase water velocities, however slightly. While the benefits of drawdown to minimum operation pool have not been conclusively verified, NMFS continues to support this action in general as one likely to benefit juvenile outmigrants. Additional text was added to FEIS Section 4.2, Fisheries Resources to provide this information.

Comment 26 *What modeling efforts have occurred previously regarding drawdown and juvenile survival?*

Response 26 Although the concept of drawdown to natural river conditions is included as a possible option under the action alternatives, the EIS clearly indicates that a separate analysis would be required if drawdown were to be pursued because of the potential for extensive environmental impacts. Although extensive evaluations have been conducted for the Lower Snake River projects relative to drawdown, no clear-cut results have been produced. In addition, because drawdown is an option for all of the alternatives, it is not an adequate factor for distinguishing between the alternatives. As a result, extensive evaluations or assessments are not conducted as part of this EIS.

However, the Quantitative Analysis Report (QAR) assessed the potential for recovery of the listed species relative to the goals of the HCPs. This assessment indicated that although the HCPs alone would not be adequate to meet the extinction risk criteria, project removal alone would also not meet the criteria. See FEIS Section 4.1.2.1, Project Area.

No Net Impact Standard Elements

Comment 27 *Several commenters requested clarification of the biological and scientific justification for the components of the no net impact standard, and the assumption that these components were additive, even though they are comprised of compensation for impacts to different life stages, and various components are not quantifiable. Others questioned whether the no net impact standard would be feasible if the 7 percent hatchery component was not guaranteed, and whether the standard is consistent with other recovery efforts in the basin.*

Response 27 The performance standards were values negotiated during the HCP development process, which included representatives of the Joint Fisheries Parties. The standards were based on the best available scientific data. As a result, the standards represent the best professional judgment of the negotiating parties. Additional information regarding the biological basis for the overall survival, hatchery compensation, and tributary funding was included in FEIS Section 2.3.4.4, HCP Performance Standards.

These performance standards were evaluated through the Quantitative Analysis Report (QAR) to determine their effects on species recovery and are summarized in Chapter 5 of the FEIS. The report compares the survival benefits of the HCP measures with the survival improvements needed to satisfy long-term recovery risk criteria. The QAR is summarized in Appendix E of the FEIS.

The PUDs committed to provide adequate funding and support to meet the full hatchery supplementation requirement described in the HCPs. Although it is NMFS's intent to allow the PUDs to provide full hatchery production through 2013, this level of production cannot, for various reasons, be guaranteed for subsequent 10-year periods after 2013 and under all possible scenarios (e.g., limitations in broodstock). Because the primary purpose of the HCP process is to protect and lead to the recovery of listed species, this goal must take precedence over the no net impact standard. As such, NMFS may be required, due to concerns about possible negative impacts of hatchery production on the recovery of the natural populations of Endangered Species Act-listed species, to restrict hatchery production to levels that do not threaten the recovery of naturally reproducing listed fish in 2013 or at subsequent 10-year intervals. However, the no net impact standard remains a goal of the HCPs, and the PUDs have guaranteed the appropriate level of hatchery funding to meet the 7 percent hatchery supplementation component of the no net impact standard. The failure to achieve no net impact would be a basis for withdrawal under the

Agreements in 2013 (2018 for the Wells Project). Formal consultation between NMFS and the Tribes on a government-to-government basis would include discussions of the hatchery issue, and would occur prior to issuance of a Record of Decision (ROD) or a final biological opinion on the HCPs.

As revised, the HCPs specify the initial hatchery production levels that will be necessary to meet no net impact. In 2013, and every 10 years thereafter (at the time of the program review), NMFS may determine that the impacts of hatchery production to the wild populations are greater than expected and ultimately require reducing production to acceptable levels (see Section 8.7.1 of the Wells HCP [Hatchery Compensation Plan] Changed Hatchery Policies Under ESA, and Section 8.8.1 of the Rocky Reach and Rock Island HCPs [Hatchery Compensation Plan, Changed Hatchery Policies Under ESA]). Should this scenario occur, the coordinating committees would ascertain the measures required to meet the no net impact standard.

The HCPs are consistent with the other recovery plans in the basin, as they focus on the key components in the recovery process. NMFS has developed guidelines for basin-level, multi-species recovery planning, which encompasses habitat, harvest, hatcheries, and hydropower. This recovery planning analysis is contained in the document entitled *Conservation of Columbia Basin Fish: Final Basinwide Salmon Recovery Strategy* (Federal Caucus 2000). Three of these four components of the recovery planning are primary components of the HCPs (harvest is the exception). Also consistent with these basinwide programs, the HCPs are multi-species programs that encompass multiple life stages.

Comment 28 *Several commenters requested clarification of how a 95 percent survival goal over 95 percent of the migration period corresponds to only a 5 percent juvenile passage mortality. Others questioned the exclusion of spring-run chinook salmon, smaller than 50 mm in length, from the 95 percent juvenile dam passage survival for the full run of that species in the event turbine intake screens are installed. There were also some suggestions for a greater habitat component and a lesser hatchery component than that proposed in the HCPs.*

Response 28 The measurement of the no net impact standard is based on the entire run, although the protection measures implemented at the projects are targeted at 95 percent of the run. Compensation through hatchery and tributary funding measures is based upon calculations derived from the average adult counts effectively representing 100 percent of the runs. Thus, mitigation is provided for 100 percent of the migration periods, but the project operations concentrate on 95 percent of the spring and summer migration periods. Recognizing that some measures are costly per unit time, the signatory parties agreed that juvenile dam passage protective measures would encompass 95 percent of the migration as an objective that could be effectively managed. This applies to the 95 percent juvenile dam passage survival standard and not the 93 percent juvenile project survival measurement. In actuality, because the spring and summer migrations overlap significantly, the juvenile spill program under Alternative 3 will most often be a continuous operation between the spring and summer periods. The spill program will, in most years, actually provide protection to more than 95 percent of the spring and summer migrants. Other measures to improve juvenile survival through the projects (Rocky Reach fish bypass system, predator control programs) are expected to cover an even higher proportion of the migrants. Implementing measures to cover 95 percent of the spring and summer migrations is consistent with the provisions of the biological opinions for the Wells, Rocky Reach, and Federal projects on the mainstem Columbia River (NMFS 2000a,b, 2002a). While the full suite of dam survival improvement measures will not cover all juveniles migrating throughout the year, these protection measures should translate into a significant survival improvement for all Plan species compared to Alternative 1, and for all unlisted species compared to Alternative 2.

The revised HCP does not include a specific exemption for spring-run chinook salmon less than 50 mm in length. However, the signatory parties recognize that some species or life histories cannot be measured with the technologies available at this time. The signatory parties are committed to evaluating the survival of these fish after the technology becomes available. The coordinating committees would be responsible for making the determination and approving an appropriate study prior to implementation.

The approach used to translate 2 percent mitigation into habitat improvements was determined by negotiation among the participants in the development of the HCP, which included agencies, Tribes, American Rivers, the applicants, and the applicants' power purchasers. The tributary habitat improvements are not intended to result in a reduction of hatchery supplementation. The initial process to determine the appropriate amount of mitigation for the tributary habitat improvement fund (Plan Species Account) was to evaluate the types and extent of habitat improvements that would mitigate for 2 percent of project mortality, and then to determine the overall cost to conduct these types of improvements. Mortality was then appropriated by project (Wells, Rocky Reach, and Rock Island), based on the numbers of fish that would be affected by each project, to ensure the appropriate commitment of financial resources. The tributary funding provided by each project represents the tributary habitat improvement mitigation measures. See FEIS Section 2.3.4.8, HCP Conservation Plan and Compensation Measures.

Shifting to a larger compensation level for the habitat component in the no net impact standard could reduce the compensation provided through the hatchery programs. While the additional tributary habitat work would be beneficial, these benefits would likely result in a gradual long-term improvement in fish production and survival. On the other hand, removing funds from the hatchery programs would result in immediate loss of hatchery fish, thereby affecting harvest opportunities. Recent changes to the hatchery programs are expected to minimize the impacts of hatchery fish on wild populations, and possibly increase wild populations with the use of wild broodstock programs. Hatchery programs have a greater potential for achieving short-term gains, while tributary funding provides long-term habitat improvements. The combination of short- and long-term components provides a balanced approach to salmon recovery, which is similar to the approach provided in the biological opinion for the Federal Columbia River Power System (NMFS 2000a).

HCP Uncertainties

Comment 29 *Several commenters expressed concerns that some portions of the standards, particularly the tributary habitat mitigation or delayed mortality, cannot be measured with the existing sampling methods. This raised the issue of whether different standards should be developed, such as project operational criteria.*

Response 29 The stated intent of the HCPs is to achieve the no net impact standard no later than 2013 (2018 for the Wells Project), with the exception of the Tributary Conservation Plan, which is not monitored. The revised HCPs clearly indicate how and when the hatchery production levels will be evaluated and adjusted, as well as the priority of survival standards and the requirements by which survival is measured (see Figure 2-4 of the FEIS). The pertinent HCP definitions clearly note that the survival standards are intended to measure project effects "including direct, indirect, and delayed mortality wherever it may occur and can be measured (as it relates to the projects) given the available mark-recapture technology." It is NMFS's opinion that these standards are most likely to be measured with existing or developing technology.

With respect to the tributary programs, the signatory parties agree that funding-approved habitat restoration and protection projects will constitute compensation for 2 percent unavoidable adult project mortality. They also agree that no effort will be made to determine whether or not the Tributary Conservation Plan is, in fact, increasing the survival of Plan species by 2 percent. Rather, future assessments of this program will be designed to ensure that the Plan Species Account is being utilized in an effective and efficient manner. This agreement recognizes that any statistical estimate of a 2 percent survival increase relative to habitat improvements would be inconclusive. Under even the most exacting experimental design, fluctuations in the natural environment alone would result in error bounds many times larger than the metric to be estimated.

Although it is possible that the standards might not be met for some or all of the Plan species at one project or another, there would be no additional mitigation requirements for not meeting the standards prior to 2013 (2018 for the Wells Project), except as set forth in Phase II, as long as the PUDs comply with HCP permit conditions. In contrast, under Alternative 2, additional mitigation could be required for listed species if new information indicates that the mitigation measures established under the initial Section 7 consultation are not adequate to ensure the continued existence of the listed species. Refer to FEIS Section 2.3.3, Alternative 2 for Alternative 2 and Section 2.3.4.5, HCP Phases and Section 2.3.4.8, HCP Conservation Plan and Compensation Measures for Alternative 3.

Current survival estimates are provided in FEIS Sections 3.2.5, Adult Survival at the Projects and 3.2.6, Juvenile Survival at the Projects at each of the hydroelectric projects. Both action alternatives require, or are expected to require, additional improvements to these survival rates except at Wells Dam where project survival for listed species already exceeds 93 percent. The Endangered Species Act criteria specify that the issuance of a permit should not "appreciably reduce the likelihood of the survival and recovery of the species in the wild" (Section 10) or does not "jeopardize the continued existence of" any Federally listed species (Section 7). There are no provisions that require a net benefit to the affected species or that the proposed action must necessarily result in the recovery of the species.

The Quantitative Analysis Report analyses suggest that the HCPs would not only satisfy the Endangered Species Act requirements, but that the HCPs would increase the probability of the recovery of listed species. However, implementation of the HCPs would not, nor are the HCPs required to, recover these species by themselves. The mitigation requirements under Alternative 2 are expected to be similar to those outlined in the HCPs because the requirements for listed species in both instances would be based on the same baseline information. Under Alternative 2, new information indicating that the measures were inadequate to ensure the continued existence of the species would likely result in reinitiation of consultation to develop additional measures to increase survival of listed species. Under Alternative 3, failure to meet the performance standards (Phase II) would result in the coordinating committees developing measures to meet the HCP survival standards. In addition, in 2013 (2018 for the Wells Project) and every 10 years thereafter, should information indicate that the stocks are not rebuilding, NMFS (after meeting several conditions of the agreement) could withdraw the permit. Thus, while the processes have obvious differences, the outcome under both action alternatives is that listed species will receive adequate protection in the long term. Under Alternative 2, protective measures for unlisted species would be attained through license reopener clauses or through relicensing while under Alternative 3, these species would immediately receive a commensurate level of protection as listed species.

Specific project configuration and operational guidelines have been the standard means of protecting anadromous fish species in the Columbia River Basin in the past. However, such guidelines do not guarantee or mandate the achievement of specific survival rates. Setting a standard for fish passage efficiency (non-turbine passage rates), for example, provides an opportunity for greater survival but does not establish a survival goal. This approach assumes that a certain percentage of the fish will pass through a specific route each year, if the project is operated in a certain manner, and includes a survival rate for that passage route (see Table 3-4 in the FEIS). In addition, this approach often relies on data from various projects or various years (e.g., average turbine passage survival) to determine route-specific survival or passage efficiency rates. As a result, there does not appear to be any more species recovery certainty with that approach compared to having a fixed, results-oriented, project passage survival goal that is measured at each project.

The HCP signatory parties recognize that current methodologies cannot differentiate between sources of adult mortality (included in the 91 percent combined adult and juvenile survival standard) within the project area. Known adult mortalities within a project boundary could be due to natural mortality (i.e., mortalities occur even in fairly pristine river systems without dams), or due to delayed or cumulative effects (e.g., catch and release angling, injuries sustained while escaping commercial or tribal fisheries, downstream Federal project impacts). The HCP signatory parties, recognizing the limitations associated with the best available technology, developed three surrogate standards for assessing the survival of juvenile fish. These are, in order of priority: (1) measured juvenile project survival (93 percent), (2) measured dam passage survival (95 percent), and (3) calculated dam passage survival. The achievement of the HCP survival standards would be determined by averaging the estimates from 3 years of valid studies. Only the survival estimates for species that cannot be measured directly (e.g., sockeye or subyearling chinook salmon) would be based on the lowest priority route-specific methodology or surrogate species (see Figure 2-4 of the FEIS). In addition, as technology advances allow, verification of survival rates measured against a higher priority standard would be required.

Comment 30 *Several commenters requested an analysis to determine whether the proposed funding for off-site mitigation is adequate, particularly because Grant County PUD is no longer part of the HCP process. Others questioned whether Alternative 2 could potentially provide greater tributary habitat improvements than Alternative 3.*

Response 30 Only Alternative 3 includes PUD funding of tributary habitat improvement projects. Funding for tributary habitat improvements is assumed to compensate for 2 percent of unavoidable project mortality. Participatory parties in the development of the HCPs (as described in FEIS Section 1.1, Introduction) worked together in determining funding levels to be provided by each PUD. This effort included an analysis of the cost of habitat easements, property acquisitions, water rights purchases, and specific restoration projects to determine the specific level of funding needed over the next 50 years.

The total amount to be provided to the Plan Species Account was originally based on a compensation level for impacts associated with the five Mid-Columbia River dams. This total amount was allocated to the different projects based on the proportion of their impacts to the stocks. For example, the Wells Project was assigned a smaller proportion of the funding responsibilities than the Rocky Reach Project because the impacts associated with the Wells Project would affect only those fish migrating to or from the Okanogan and Methow Rivers. In addition to impacting these same stocks, the Rocky Reach Project would also impact the Entiat River stocks. Although the overall size of the fund was reduced when Grant County PUD elected to not pursue a Section 10 permit, the compensation level remains unchanged for the remaining

projects. It is assumed that mitigation alternatives resulting from the Section 7 consultation for the Grant County PUD projects will replace the compensation that was lost from the HCP Tributary Fund for the listed species. There is no basis under the Endangered Species Act for Chelan and Douglas County PUDs to be required to mitigate for impacts attributable to the Grant County PUD projects.

Note that hatchery compensation levels determined for each PUD are also independent of the other PUDs, including Grant County PUD. These compensation levels are based on estimates of impacts associated with each individual project and not on a region-wide basis. Therefore, Chelan and Douglas County PUDs would still provide up to 7 percent hatchery compensation for the unavoidable mortality associated with their projects.

An estimate of $100 million was originally established as the funding level to the Plan Species Account, assuming the participation of all three of the Mid-Columbia PUDs. This was allocated based on the degree of impacts to the species for each project. Because Grant County has opted not to pursue an HCP, the mitigation funding for impacts related to Wanapum and Priest Rapids dams are no longer included in the overall HCP funding. According to the HCP terms and assuming that the performance standards are met, Douglas County would make an initial payment of $1,982,000 plus $176,178 annually for 45 years. Chelan County would contribute $229,800 annually for 50 years for the Rocky Reach Project and $485,200 annually for 50 years for the Rock Island Project. In addition, the HCPs provide mechanisms for accelerating payments so that more funds are available in the early years of the HCPs. Total funding would be $46,660,010 in 1998 dollars and the annual payments will be adjusted for inflation. If adult survival through Wells Dam is assessed and determined to be less than 2 percent and the combined adult and juvenile project survival is greater than 91 percent, then the annual funding to the Plan Species Account for the Wells Project would be reduced proportionately (see Example 1, Wells HCP, 2002. Chelan County funding levels would not change whether or not the performance standards are met. Therefore, the current funding level represents a substantial source of habitat improvement funding even without the Grant County portions. Refer to FEIS Section 2.3.4.8, HCP Conservation Plan and Compensation Measures.

In addition, Endangered Species Act Section 7 consultations have been completed for the Lower Columbia River dams (NMFS 2000a) and are in the process of being completed for the Grant County PUD dams (NMFS expects to produce a final biological opinion prior to 2003). Therefore, these projects are, or soon will be, responsible for meeting survival levels to avoid jeopardizing listed species. Under Alternative 3, should the stocks fail to rebuild by 2013 (2018 for Douglas County), NMFS could take steps to withdraw the permit, and would undoubtedly request that Grant County PUD and the Federal operators reinitiate consultation on the other four Columbia River projects and four Snake River projects.

It is not practical or efficient to attempt to quantify a 2 percent compensation level for the habitat improvement projects. Even under the most exacting experimental design, fluctuations in the natural environment alone would result in error bounds many times larger than the metric to be estimated. This determination is based on the diversity of potential projects, the varying time frames for the maximum benefit to occur for these different projects, and the overall difficulty and expense of monitoring the benefits. However, each improvement project would be monitored to ensure that the site-specific goals and objectives are obtained. The revised HCPs each contain a Tributary Assessment Program in addition to the tributary funding discussed above. The Tributary Assessment Program will monitor and evaluate the relative performance of the tributary enhancement projects approved by the tributary committees.

Comment 31 *Please confirm that the HCPs and Quantitative Analysis Report require that the performance standards will be applied regardless of cost or drought, and that these factors will not impact improvements to the lower river projects. This should include an assessment of the 2001 water year. The EIS should also assess the level of survival improvement needed to sustain Tribal harvests well above recent restricted levels.*

Response 31 Only one section of the HCP notes conditions under which the PUDs might fail to implement HCP measures. In Section 12.7 of the HCPs [Miscellaneous, Force Majeure], "*force majeure*" is defined as "causes beyond the reasonable control of, and without the fault or negligence of, the PUD or any entity controlled by the PUD, including its contractors and subcontractors." The HCPs further stipulate that "economic hardship shall not constitute *force majeure* under this Agreement." Thus, *force majeure* would apply to events such as attacks due to war or terrorism, major equipment failure, or damage from earthquakes or floods; but would not apply to a conscious decision by a PUD to curtail HCP measures to realize economic benefits. This would be cause for withdrawal by the signatory parties. Furthermore, the HCPs are not connected to Endangered Species Act requirements at other hydroelectric projects on the Columbia River and therefore will not affect the implementation of measures at lower river projects to improve juvenile or adult salmon or steelhead survival.

The drought conditions in 2001 resulted in lower spill levels at a number of Columbia and Snake River hydroelectric projects than has been was generally stipulated or recommended to aid the downstream migration of anadromous fish in biological opinions. At that time, the Chelan and Douglas County PUDs voluntarily implemented some provisions of the agreements although they were not bound by the terms of the HCPs, although they have voluntarily implemented some provisions of the agreements to enhance the possibilities of meeting the HCP survival standards. The results in 2001 indicate the benefits of the HCPs as strong incentives to maintain fish protection programs. If In future years, should the PUDs fail to meet the requirements of the HCPs, it would provide Signatory Parties cause for withdrawing from the agreement and NMFS cause for withdrawing jeopardize their incidental take permits. Under the existing licenses and operational agreements, which include Section 7 consultations for most of the Columbia and Snake River projects, the incentives are not as strong, as evidenced by the reduced spill levels that were provided in 2001.

Refer to responses to Comments #40 and #52 concerning survival standards, Tribal harvest, and the role of hatchery supplementation in assuring Tribal harvest priorities. However, the provisions of the Endangered Species Act do not require the recovery of the species to harvestable levels. This applies to both action alternatives.

Range of Alternatives

Comment 32 *Several commenters indicated that the EIS does not analyze an adequate range of alternatives, or compares and contrasts these alternatives in a complete and unbiased manner. Others questioned the idea that Alternative 2 could take longer to implement than Alternative 3.*

Response 32 The FEIS includes (1) a no-action alternative (Alternative 1), (2) a hydropower conservation measures alternative (Alternative 2), and (3) proposed habitat conservation plan alternative (Alternative 3). Alternative 1 is based on existing conditions (Wells and Rock Island Settlement Agreements and the Rocky Reach Fourth Revised Interim Stipulation) representing the baseline of comparison for the action alternatives and the position that no action is taken either under Section 7 or Section 10. Alternative 2 represents measures that were considered during the development of the proposed action, as well as certain measures raised in public comments on the

DEIS. Alternative 3 represents measures contained in the proposed HCPs. Some alternatives raised in public comments were discussed but eliminated from detailed study. The three alternatives considered in detail represent the range of actions that could reasonably occur at the three hydroelectric projects. The EIS attempts to present the alternatives without bias; however, there is some overlap of both the protective measures used to lower mortality and their implementation in Alternatives 2 and 3, especially with respect to actions taken to protect listed Plan species. There is some regulatory duplication in the implementation processes of Section 7 and Section 10.

Both action alternatives include a variety of measures to be implemented at the projects for reducing Plan species mortality. The primary differences between the action alternatives are (1) the extent (proportion of juvenile migration covered) and level (percentage of spill) of the spill programs at each project, and (2) the choice of passage route (6,000 cfs sluiceway or juvenile collection and transport system) at Chelan County PUD's Rocky Reach Project. The description of the action alternatives also identifies relative differences with respect to regulatory procedures, the length of time that might be required to implement alternative measures, and the likelihood of implementing the protective measures for listed and unlisted Plan species. Procedural differences are described in FEIS Section 2.6, Alternative Comparison, in Tables 2-7 and 2-8, and in Chapter 4. Table 2-7 compares differences between the procedures for complying with the Endangered Species Act, while Table 2-8 illustrates the environmental differences that would occur from implementation of the alternatives, as well as the no-action alternative. Revisions to the DEIS have been included to more clearly display the differences among the alternatives. All alternatives were given equal weight, consideration, and review for selection of a preferred alternative.

The mitigation measures proposed at the dams under Alternatives 2 and 3 are expected to be similar and yield similar results for listed Plan species. Alternative 3 is expected to provide more protection, compared to Alternative 2, for unlisted Plan species.

The two primary mitigation measures proposed under Alternative 3 are hatchery supplementation (which represents mitigation for 7 percent project mortality), and funding for tributary habitat improvements (which represents mitigation for 2 percent project mortality). It is important to note that the majority of the hatchery production in the Upper Columbia River is designed to compensate for original inundation by the projects. This production is not subject to adjustment through the HCPs. The initial production levels are detailed in Section 8 of the HCPs, Hatchery Compensation Plan. Hatchery production under Alternative 2 would be addressed through the existing settlement agreements or during relicensing, and through the issuance of direct and incidental take permits to WDFW, which operates the PUD-funded hatcheries.

For the Wells Project and existing settlement agreements between FERC and the Douglas County PUD, ongoing hatchery production of spring and summer chinook salmon and steelhead currently mitigates for an assumed 14 percent level of mortality at the project (Alternative 1). Under both Alternatives 2 and 3, the production of yearling (spring) chinook salmon and steelhead would be reduced to 3.8 percent, based on the 3-year average of juvenile project survival studies (96.2 percent). Under Alternative 3, the remaining Permit species will be compensated at the 7 percent level. The need for coho salmon compensation will be assessed in 2006 and will be based upon the development of either a long-term coho salmon hatchery program and/or the establishment of a threshold population of naturally reproducing coho salmon in the Methow Basin. Should coho salmon compensation be warranted, Douglas County PUD would implement a program to provide the equivalent of 3.8 percent juvenile mortality. This level is based on the agreed-upon

interim value for juvenile project survival for coho salmon, which at this time is best estimated by the yearling average chinook salmon and steelhead survival estimates.

For the Rocky Reach and Rock Island projects, under the HCPs, Chelan County PUD would provide the funding and capacity to meet the 7 percent hatchery compensation level necessary to achieve the no net impact standard for all Plan species. However, Chelan County PUD has agreed to continue meeting their existing hatchery obligations through 2013, during which time they will evaluate options for the long-term production of sockeye salmon. Thus, the 7 percent HCP production requirement will be exceeded for some Plan species (steelhead, spring-run chinook salmon) through 2013, but will not be met for other Plan species (sockeye and coho salmon). Hatchery compensation levels for these projects would be adjusted in 2013, including 7 percent hatchery compensation for sockeye salmon (after options have been evaluated) and possibly for coho salmon (compensation timelines and decision points are identical to those identified above for Douglas County PUD).

In summary, for hatchery compensation, Alternatives 1, 2, and 3 are expected to be identical at least through 2013. After 2013, production levels for listed species would likely decrease from this baseline level for both Alternatives 2 and 3. Alternative 3 would provide 7 percent hatchery compensation for sockeye salmon and potentially for coho salmon, which is not contemplated in either Alternative 1 or 2.

The mitigation measures for the tributary habitat improvements under Alternative 3 are represented by the funding levels, rather than specific projects that would be funded. The tributary committees have the responsibility to select the projects to be funded by the Plan Species Account. The tributary committees will consist of representatives from the signatory parties (as voting members). In addition, the tributary committees may select other expert entities (such as land and water trusts or conservancy groups) to serve as additional, non-voting members of the committees. This format ensures that a wide range of perspectives are incorporated and biologically sound decisions are made. Alternative 2 does not include any off-site mitigation in the form of PUD-funded tributary habitat improvement projects (see FEIS Section 2.6.6.2, Alternative 2).

The length of time it has taken for Section 7 consultation from initiation to implementation of conservation measures has averaged over 5 years for Mid-Columbia projects owned by PUDs, due to FERC's current interpretation of their responsibilities under the Endangered Species Act and legal options open to the applicants. Some of these processes have resulted in a biological opinion on interim operations, resulting in consultation reinitiation prior to the expiration date of the interim operations. Section 7 consultation would also be required at relicensing or any license reopener proceedings. During these consultation proceedings, the existing mitigation programs would proceed until final resolutions were reached on additional conservation measures required. As described in FEIS Section 2.6.5, Implementation Schedule, the HCPs were developed to minimize legal options and expedite project actions that directly benefit the Plan species. Actions would be taken from the perspective of cooperation and coordination, rather than a series of independent actions and processes that would be subject to litigation. Compared to Alternative 2, the initial protection measures under Alternative 3 would be implemented immediately. Future implementation of any additional tools needed to meet the survival standards under the HCPs would likely be implemented, for the reasons stated above, in a more timely manner than would be the case under Alternative 2.

No-Action Alternative

Comment 33 *Several commenters questioned the appropriateness of the no-action alternative, particularly since it does not include the normative river as the baseline conditions, and that it omits statutory authorities at relicensing. Others questioned whether the existing mitigation and compensation levels are adequate to mitigate for dam construction and operations.*

Response 33 Alternative 1 (the no-action alternative) represents existing baseline conditions that would occur if neither action alternative were implemented, which is consistent with NEPA requirements. Alternative 1 is evaluated in Chapter 4 of the FEIS (which describes effects of the alternatives), similar to the evaluation of Alternatives 2 and 3. Relicensing is a separate independent action with FERC as the lead agency, and includes more than fish protection measures for listed species. Therefore, Alternative 1 was limited to existing FERC licenses and settlement agreements that govern current operations, with one exception. FERC has amended the Rocky Reach Project license to allow for the construction and operation of a juvenile bypass facility at that project. Since this measure is rightfully considered an element of the HCP, evaluation of the juvenile bypass facility occurs under Alternative 3 rather than under Alternative 1. Alternative 1 also provides a baseline for comparison with the action alternatives.

Long-term settlement agreements have been negotiated for the Wells and Rock Island dams that include the hatchery mitigation provisions as compensation for project inundation and existing ongoing impacts. Although a long-term agreement has not been reached for Rocky Reach, this dam has operated from 1979 to 1997 under various stipulations. Initial inundation losses were established from estimates of spawning habitat loss. The initial inundation compensation did not mitigate for passage loss of juveniles. The long-term settlement agreements at Wells and Rock Island Dams established passage loss rates, thus completing the mitigation package for project impacts to salmonids. Because of these relatively recent reevaluations of the mitigation programs at all three projects, it is reasonable to assume that existing mitigation or compensation levels are adequate to address project inundation, at least for the purposes of comparison within this FEIS.

Action Alternatives

Comment 34 *Several commenters requested clarification of the legal and management authorities associated with Alternative 2 that would not be available under Alternative 3. Several commenters suggested that adaptive management would be more effective under Alternative 2. Other commenters requested additional information in Table 2-8 of the DEIS summarizing the comparisons between alternatives, how the Quantitative Analysis Report (QAR) information is incorporated into the alternatives, and why the HCPs do not consist of an ecosystem approach to recover the species.*

Response 34 The HCPs would not affect the PUDs' responsibilities under other Federal, State, Tribal, or local statutes. In addition, parties that do not sign the HCPs can pursue these Federal, State, or local statutes if they are in disagreement with the PUDs' approach in implementing the mitigation measures associated with the HCPs. However, as a result of an agreement with USFWS, NMFS is the only agency with mandatory conditioning authority for the listed anadromous fish species under the Federal Power Act and the Endangered Species Act. FERC could require additional mitigation measures during relicensing procedures, although if these additional measures were inconsistent with the HCPs, the parties could withdraw from the agreements.

These comments were generally associated with the ability for resource agencies and Tribes to pursue reservoir drawdown, dam removal, or other viable non-power options to recover the

species. See FEIS Section 2.6, Alternative Comparison that discuss the application of the protection provisions of other laws and statutes for the two action alternatives. These other laws and statutes would be available to non-signatory parties to the HCPs to protect Mid-Columbia River fish stocks. See Table 2-8 of the FEIS to reflect the protection provisions of other laws. The results of the analyses conducted for this project indicate that dam removal would not meet the extinction risk criteria if recent environmental conditions continue.

The QAR analyzes the HCP fish protection measures combined with other foreseeable protection measures expected to occur at other Columbia River projects. Because fish protection measures are expected to be similar between Sections 7 and 10 for listed species, the report results describe long-term risks associated with both alternatives. The HCPs are an appropriate vehicle for supporting adaptive management. The HCPs are based on a results-oriented approach that requires an adaptive management approach to reach the survival goals. Alternative 3 provides a systematic and regular process for evaluating and reevaluating survival rates for all Plan species at the projects to facilitate adaptive management opportunities. Under Alternative 2, evaluations would likely be of a similar scope, but would focus primarily on listed species.

The decision not to use an overall ecosystem-based management approach in developing the HCP occurred in the early 1990s, and was not developed in further detail because it was determined to be too difficult and costly to obtain quantitative information on the effects of the projects on all of the fish and wildlife species that occur within the vicinity of the projects. The decision was then made to concentrate on a multi-species level as opposed to an ecosystem level with all species present in the project area. This resulted in focusing on Endangered Species Act-listed anadromous fish species that would be considered under Section 9 of the Endangered Species Act, as well as the unlisted species for which NMFS is the responsible reviewing agency.

Dam Operations-Related Questions

Comment 35 *Several commenters requested clarification on the fish bypass options that could occur under the different alternatives, their potential effectiveness, and their impacts to non-Plan species. These options include turbine intake screens, spill, and surface collection systems.*

Response 35 Bypass options (methods of passing fish using non-turbine routes of passage) include the construction and operation of structures specifically designed to provide safe routes of passage to migrating fish on one end of the spectrum and voluntary release of water through spillways at the other end. Structural remedies (including turbine intake screens and surface collectors) are typically limited by constraints resulting from the unique characteristics of each project, while spill is most often limited by total dissolved gas restrictions. At present, a combination of bypass systems and spill levels appear to provide the most effective fish bypass systems at mainstem Columbia River projects. Furthermore, until issues relating to water quality impacts and the overall effectiveness of spill are resolved and determined, there is no indication that spill will be the only measure to be used to aid in increasing survival rates of juveniles passing the dams.

Bypass systems, spill, or some combination of these measures are currently being used to aid fish passage at the Mid-Columbia River projects, and would therefore likely be required at the PUD projects under either Alternative 2 or 3. Douglas County PUD has already developed a spillway bypass system at the Wells Project that has been in operation for over a decade. Chelan County PUD has recently received a FERC order (issued after consulting with NMFS) allowing the construction and operation of a screened bypass system at the Rocky Reach Project, which is expected to be operational prior to the 2003 migration. Spill is expected to continue at the Rocky Reach Dam to supplement the bypass facility. No bypass system is currently under consideration

for the Rock Island Project, although bypass systems have been tested at both power houses at Rock Island in the past. A bypass system would likely be considered at the Rock Island Project should proposed measures (including a 20 percent spill rate) fail to meet survival requirements under either action alternative.

Protection of non-Plan species (e.g., lamprey, sturgeon, and bull trout) would occur in the same manner under both action alternatives. Section 7 consultation would occur for bull trout under both Alternatives 2 and 3 (as it is a listed species), while protection for other species would occur through compliance with the Federal Power Act.

The FEIS describes procedural differences between the alternatives and how these might differentially affect the Plan species. In addition, survival rates for the various fish passage routes at the projects are discussed, but the fish protection tools that may be used to achieve performance standards are not specified. Under Alternative 2, NMFS would issue FERC a biological opinion on a proposed Federal action. If NMFS determined that the proposed action would jeopardize the continued existence of the listed species, NMFS would provide a reasonable and prudent alternative that describes the fish protection measures necessary to avoid jeopardy. For Alternative 3, the PUDs would select the methods for achieving survival under Phase I. The coordinating committees would select the methods under Phase II. These decisions would likely change over time, depending on subsequent evaluations and the development of new technologies for measuring survival standards.

The benefits and disadvantages associated with installing screens are discussed in FEIS Section 4.2.3.2, Other Plan Species. For Alternative 2, specific protective measures for listed species would likely occur through Section 7 consultations and FERC license amendments. For unlisted species (salmon and other aquatic species), protective measures would be pursued primarily through Federal Power Act processes (relicensing procedures or amendments to the existing licenses). For Alternative 3, the Plan species would be protected by the same no net impact standard as the listed species. This would include satisfying the 95 percent juvenile dam passage, 93 percent juvenile project passage, or 91 percent combined adult and juvenile total project passage survival standards. Under Alternative 3, the protective measures would occur immediately for all species, while under Alternative 2, the protective measures could be delayed through litigation (this is particularly likely in the case of unlisted species). Under Alternative 2, it is also more likely that less protective measures (for example, lower spill levels or a shorter duration of spill) would be implemented for unlisted species than for listed species. Under both alternatives, other species would be protected through other processes, such as FERC relicensing and Endangered Species Act consultation (should the fish species become listed in the future).

Comment 36 *Several commenters requested additional information on recent estimates of juvenile mortality rates specific to passing the projects, as well as the effects of project operations on adult salmonids.*

Response 36 Project survival studies better estimate direct, indirect, and delayed effects than dam passage or passage route-specific studies, because the studies typically span a longer time period and account for some variability in passage conditions through the outmigration season. Passage route-specific evaluations rarely estimate indirect and delayed effects because the evaluations typically occur over a shorter time frame and test specific or limited operational conditions. As a result, these latter evaluations might not be as representative of the typical or average passage conditions experienced by the species. However, for some species it will not be possible to conduct project survival studies due to the limited number of fish available for the studies and their body size

relative to the tagging method required. In these cases, verification would likely be through studies with representative species.

The revised HCPs identify the calculation of dam passage survival (based on assumed passage and survival parameters) as a measurement of last resort. If at all possible, juvenile project survival or dam passage survival of Plan species would be measured through specific survival studies. Of these three options, only by meeting the 93 percent juvenile project survival standard can a PUD receive a Phase III (Standard Achieved) determination. The emphasis has been shifted from dam passage survival (measured or calculated) to project survival estimates (see Table 3-4 of the FEIS). Thus, the verification of survival under either action alternative would likely rely on project survival studies rather than passage route-specific studies.

Turbine survival data do not exist for all species at the PUD projects, and the available data are primarily estimates of direct mortality established through balloon-tag studies. These estimates do not fully take into account indirect or delayed mortality due to potentially increased predation susceptibility resulting from the effects of turbine passage. In addition, some of the data were collected before recent changes at the projects (turbine modifications to increase survival) were completed. Therefore, additional data from other sources were used to establish average baseline conditions. The numbers included in Table 2-4 represent a composite of relevant data for specific projects or similar projects in the basin.

The Federal Columbia River Power System biological opinion (NMFS 2000a) concluded that, although power peaking can affect spawning adults, egg incubation, and fry rearing stages, power peaking alone does not have a significant adverse effect on migrating salmon at the mainstem Federal projects.

Peak turbine efficiency refers to conditions that minimize the turbulence and cavitation of water passing through the turbines, resulting in greater power production. These conditions are believed to produce better conditions for fish passing through the unit by minimizing pressure differences caused by these factors, which can injure or kill fish. References were changed throughout the FEIS to refer to "peak power efficiency" and text was added to FEIS Section 2.2.2, Dam and Reservoir Operations explaining the concept.

Refer to Comment #58 for a discussion of adult passage, adult survival standards, and the effects of project operations on adult passage.

Tribal Issues – Legal Responsibilities

Comment 37 *The HCPs address the Endangered Species Act, but NMFS and other Federal agencies also have duties and obligations to fulfill trust responsibilities toward Tribal trust resources. In particular, the Secretarial Order 3206 also requires that the agencies ensure that the Tribes not bear a disproportionate share of the conservation burden for listed species (Section 5, Principle 3). In addition, the Federal Government's responsibility to manage trust resources would be transferred to non-Federal entities who are not accountable for breaches of Federal trust and treaty obligations.*

Response 37 The HCPs specifically recognize Federal obligations to protect Tribal treaty/trust resources, and state in the Miscellaneous sections (Section 12.11 [Miscellaneous, Indian Tribal or Treaty Rights] of the HCPs) that "[n]othing in this agreement is intended to nor shall it in any way abridge, limit, diminish, abrogate, adjudicate, or resolve any Indian right reserved or protected in any treaty, executive order, statute or court decree. This Section shall be deemed to modify each and every

Section of this Agreement as if it is set out separately in each Section." Additional protections are also described in HCP Sections 12.12 and 12.13 [Miscellaneous, U.S. v Oregon and No Precedent/Compromise of Disputed Claims]. Formal consultation between NMFS and the Tribes on a government-to-government basis will include discussion of these issues, which would occur prior to issuance of a Record of Decision (ROD) or a final biological opinion on the HCPs. It is the intent of NMFS that the HCPs will aid in increasing the wild stock of anadromous fish over time, thereby allowing for an increased Tribal take of hatchery fish when the wild stocks reach minimum escapement levels necessary for recovery. The relationship between the proposed HCPs and the Federal Government's Tribal treaty trust responsibilities is discussed in FEIS Section 4.12.17, Legislation Pertinent to Tribal Governments.

During preparation of the HCPs, the Tribes have been continually informed and invited to participate. The Tribes participate directly and through the Bureau of Indian Affairs and the Columbia River Inter-Tribal Fish Commission. The five principles of the 1997 Secretarial Order #3206 (American Indian Tribes and the Endangered Species Act) have been followed in development of these agreements. These principles are (1) working directly with the Indian Tribes on a government-to-government basis to promote healthy ecosystems, (2) recognizing that Indian lands are not subject to the same controls as Federal public lands, (3) assisting Tribes in developing and expanding Tribal programs so that healthy ecosystems are promoted and conservation restrictions are unnecessary, (4) being sensitive to Indian culture, and (5) making available to Tribes information related to Tribal trust resources and Indian lands and to facilitate the mutual exchange of information.

Principle 3 of Secretarial Order 3206 also includes the following components: (A) the Departments shall take affirmative steps to assist Indian Tribes in developing and expanding Tribal programs that promote healthy ecosystems, (B) the Departments shall recognize that Indian Tribes are appropriate governmental entities to manage their lands and Tribal trust resources, and (C) the Departments, as trustees, shall support Tribal measures that preclude the need for conservation restrictions. Although the HCPs are not Tribal programs, the anadromous fish within the Columbia River are considered a traditional Tribal treaty resource. Implementation of the HCPs is intended to support a comprehensive strategy for protecting and recovering the five Plan species that pass through the three dams (Wells, Rocky Reach, and Rock Island), thereby promoting a healthy ecosystem. The conditional implementation strategy under Alternative 3 was developed to ensure a speedy recovery relative to Alternative 2 (refer to FEIS Section 2.6.5, Implementation Schedule), where lengthy legal proceedings may occur if FERC or the PUDs disagree with NMFS's decisions on the actions needed to ensure survival and recovery of listed species. Alternative 3 sets specific time limits on decision-making procedures and restricts the abilities of all the signatory parties to seek legal remedies to outstanding issues that may impede decision-making progress and implementation of needed conservation measures to improve survival.

Management of Columbia River Basin listed anadromous fish species would continue to be under the authority of NMFS under all alternatives. The HCPs (Alternative 3) are limited to meeting specific performance standards for the Plan species passing through the hydroelectric structures associated with the Wells, Rocky Reach, and Rock Island dams. As described in the Quantitative Analysis Report (QAR), the actions associated with Alternative 3 are a single component of a series of recovery actions planned by NMFS to recover listed fish species. Implementation of either Alternative 2 or 3, alone, is not expected to recover these fish. All other aspects of the trust responsibilities and treaty obligations are maintained by NMFS.

Comment 38 *If the Permit species continue to decline, and the PUDs are fulfilling their obligations under the HCPs, how will NMFS ensure that the agency fulfills its trust responsibility for providing harvestable fish populations? The EIS should include an analysis of this possibility and the effect of the No Surprises policy on NMFS's trust responsibility.*

Response 38 The revised HCPs acknowledge that the Services (NMFS and USFWS) could withdraw from the HCPs and NMFS could revoke a permit (even if the project has achieved and maintained the no net impact standard) if the Plan species are not rebuilding and the project is a significant factor in the failure to rebuild (see Section 2.2.1 of the Wells HCP [Termination Automatic Termination Events] and Section 2.1 of the Rocky Reach and Rock Island HCPs [Withdrawal From Agreement, Enough Already). This could occur after 2013 at the Rocky Reach and Rock Island projects and after 2018 at the Wells Project.

Comment 39 *Alternative 3 may expose the Federal Government to liability for failing to sufficiently manage and protect the Tribes' treaty-reserved resources because NMFS would be required to carry the burden of proof in a dispute resolution process with time and evidentiary limitations. Alternative 3 effectively and impermissibly transfers NMFS's management authority to project operators, thereby violating its trust responsibility to the Tribes and perhaps exposing the Federal Government to liability for failing to properly manage treaty-reserved resources.*

Response 39 In response to the Tribes' comments, the revised 2002 HCPs deleted the language that was contained in the 1998 HCPs where NMFS or any other party bringing an action to enforce the HCPs had the burden of proof. The entire dispute resolution provision of the revised HCPs was removed, with the exception of a requirement that disputes first be addressed at the technical level in the coordinating committees and then at a policy level in the policy committees prior to bringing forth any legal proceedings. The revised HCPs changed the approach used to make decisions under the HCPs. Decisions are subject to unanimous agreement by all parties to each of the various committees; thus, each party retains the authority to effectively veto any action or decision. If a resulting dispute cannot be resolved through technical and policy level meetings or voluntary, non-binding mediation, any party may exercise whatever right it may otherwise have under applicable law. Furthermore, NMFS has the discretion to enforce compliance with the HCPs and its permits. The HCPs do not limit any responsibility or obligations of NMFS to the Tribes. The revised HCPs state that the withdrawal and termination provisions are not subject to the No Surprises policy.

Tribal Issues – Harvest

Comment 40 *The HCPs lack assurances that the 7 percent hatchery compensation will be achieved or allowed, which is necessary to produce sustainable and harvestable fish populations.*

Response 40 Although the tools used to reduce salmon mortality through the dams under the HCPs (Section 10 [Endangered Species Act Compliance] 10) may be different than those used under Section 7, the overall goals of reducing mortality are the same. Therefore, there are no expected differences in the amount of harvestable fish available to Tribes between the action alternatives. The purpose of either a Section 7 or Section 10 consultation is to allow for the "incidental take" of endangered and threatened species so that an applicant is exempt from take prohibitions under Section 9 of the Endangered Species Act. The PUDs have voluntarily included in the HCPs a commitment to rebuild stocks of unlisted species to sustainable, harvestable populations; however, the utilities are not required to conduct this effort under either Section 7 or Section 10 of the Endangered Species Act.

The HCPs attempt to balance the conservation of Endangered Species Act-listed and unlisted anadromous Plan species with the Federal Government's treaty trust obligations to provide meaningful Tribal harvest, on both a short- and long-term timeframe. This includes the difficulties of providing these harvest opportunities under the harvest rate restrictions for Endangered Species Act-listed species in a mixed stock fishery. The harvest element of the Columbia River Basinwide Salmon Recovery Strategy (Federal Caucus 2000) states that there is "no more important harvest reform than discontinuing the former practice of overfishing natural fish to fully harvest hatchery fish." The strategy further states that, "Unless and until more effective selective fishing techniques are used, it will be difficult or impossible to fully realize the benefits of hatchery programs."

The Columbia River Basinwide Salmon Recovery Strategy recommends that the overall harvest rate of Upper Columbia River spring-run chinook salmon continues to be capped at 6 to 9 percent, depending on the run sizes of natural origin fish. This harvest rate is primarily intended to accommodate a base level fishery for the Tribes. Thus, under this recovery strategy, the Tribal harvest will continue to be limited by the abundance of naturally produced adult fish, unless effective selective harvesting techniques are developed. For example, the harvest of the relatively large runs of hatchery spring-run chinook salmon in the last 2 years has been limited by the relatively low abundance of naturally spawned fish.

The HCPs are intended to protect, enhance, and restore the populations and habitats of not only the Endangered Species Act-listed species but all Plan species for the purpose of establishing and maintaining naturally spawning populations that are capable of supporting a sustainable fishery. Establishing stable, naturally spawning populations capable of supporting a fishery will also allow greater harvest rates on hatchery stocks. Therefore, goals developed to maximize the opportunities to harvest hatchery fish and rebuild the naturally spawning populations are expected to enhance the harvest opportunities for both Tribal and non-Tribal fishers. These goals would satisfy both the specific provisions of the Endangered Species Act and the Federal trust responsibilities.

Balanced with the fundamental need to protect the naturally spawning populations, is the need to compensate for unavoidable mortality associated with the PUD hydroelectric projects. The HCPs propose hatchery supplementation to mitigate for 7 percent unavoidable mortality associated with each project. However, it is unknown at this time whether that level of supplementation will increase harvest opportunities or lead to the recovery of Endangered Species Act-listed species. It is also possible that 7 percent hatchery supplementation will result in the continued decline in natural spawning populations due to the negative influences that hatchery fish can have on wild stock. These negative influences may include competition for food and space, disease transmission, direct predation, and a decrease in genetic diversity.

Many Columbia River hatchery programs were originally started to replace natural production losses associated with hydroelectric development, but not necessarily to protect or rebuild natural populations. Recent changes in the goals and practices of these hatchery programs focus on producing fish that pose a lower risk to natural populations. This is accomplished by either minimizing the negative interactions with natural populations or using natural broodstocks. This has lead to an increased reliance on natural broodstocks to fulfill hatchery program needs. Nevertheless, it is recognized that the recovery of natural populations cannot be achieved simply by releasing more hatchery-produced fish, regardless of their ancestry or fitness.

Because of the wide range of scientific and policy opinions regarding the purpose and appropriate use of artificial production in specific circumstances, NMFS recommends a variety of hatchery

strategies, coupled with an adaptive management approach. Therefore, NMFS is unable to guarantee a 7 percent supplementation rate throughout the term of the 50-year agreement, although their goal is to achieve this rate whenever possible. To provide some level of assurance to the Tribes on this issue in the near future, the signatory parties revised several components of the Hatchery Compensation Plan. First, the parties detailed the initial production levels that must be obtained to meet the no net impact standard for each project. Second, the parties agreed that hatchery production commitments, except for original inundation mitigation, shall be adjusted in 2013 and every 10 years thereafter to achieve and maintain no net impact. Thus, production levels, including those initially specified in the HCPs, shall be stable for 10-year intervals. This alteration was made to both provide greater assurances to the Tribes with respect to production levels (and harvest opportunities), and to allow sufficient amounts of time to pass (approximately 2 to 3 generations) to assess the effects of previous changes to the hatchery programs. Furthermore, the supplementation programs contained in the Rocky Reach and Rock Island HCPs through 2013 are double that which is necessary to contribute 7 percent toward no net impact. In addition, in response to requests from the Tribes, the revised HCPs expressly provide for supplementation programs for coho salmon and Okanogan Basin spring-run chinook salmon.

Comment 41 *NMFS should also take into consideration the factors that led to the initial decline of salmon and steelhead, and provide analyses that examine the impacts that the various alternatives would have on the sustainability of the salmon populations and the ability of such populations to meet broad (beyond mere Endangered Species Act) recovery goals. The EIS should include a quantitative analysis of take for listed species under the proposed alternatives and the probability of reaching sustainable populations that provide harvestable surpluses for treaty and non-treaty fisheries. The EIS should include survival, recovery, and delisting goals relative to sustainable and harvestable populations for anadromous fish.*

Response 41 NMFS must comply with NEPA and Council on Environmental Quality (CEQ) regulations in the preparation of this EIS on NMFS's decision to issue the requested permits under Section 10 of the Endangered Species Act. In the context of decisions before NMFS, there is no requirement to evaluate factors for the decline of salmon and steelhead. Such an analysis was conducted by NMFS in its status reviews of Upper Columbia River salmon and steelhead populations, and in its listing decisions for Upper Columbia River steelhead and spring-run chinook salmon.

When conducting the formal consultation on the issuance of the permits described in this FEIS, NMFS is required to analyze the effects of past and ongoing human and natural factors leading to the current status of the listed species, its habitat, and ecosystem, within the action area. In formal consultation pursuant to Section 7(a)(2) of the Endangered Species Act, NMFS must also determine whether or not the proposed action is likely to "jeopardize the continued existence of any listed species," defined as, "to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species" (50 CFR Part 402.02 – Definitions). The Quantitative Analysis Report (QAR) analysis was designed specifically to provide NMFS with the necessary information to make such an assessment. The analysis contained in the QAR exceeds the level of detail required by NEPA and CEQ's regulations. A summary of the QAR is attached to the FEIS (Appendix E) and was considered in its preparation.

Harvestable populations cannot be defined adequately for the purpose of conducting a quantitative analysis. Some might argue that, because some level of treaty and non-treaty harvest is currently allowed (varying by year, location, and adult return estimates) even while many populations in the Columbia River Basin are listed, the populations are currently harvestable.

Others might argue that harvestable populations are best defined by population levels equal to historic (pre-European) levels.

When making decisions to correct the decline of salmon and steelhead, NMFS will comply fully with all applicable Federal laws and executive orders. These include trust responsibilities applicable to the unique and longstanding relationship between the U.S. Government and the region's Federally recognized Indian Tribes. The QAR established interim recovery goals for the listed species and determined the probability of achieving these goals with the HCP performance standards (see Chapter 5 of the FEIS and Appendix E). These recovery goals included current harvest levels. NMFS views meeting these standards as a critical step in recovering the listed species to levels that will allow future increases in treaty and non-treaty harvest opportunities. Under Alternative 3, the same performance standards are set for both listed and unlisted Plan species.

Survival rates of juvenile and adult fish passing the projects are estimated in FEIS Section 2.2.3, How the Dams Affect Migrating Fish and Table 3-4 [Calculated Juvenile Fish Passage Survival Estimates by Passage Route], representing the baseline level of "take." Specific performance standards for reducing this take and the methodology for evaluating the level of take over time are set in Alternative 3.

Tribal Issues – No Surprises Policy

Comment 42 *The No Surprises policy should be extended to the Tribes, and provisions should be included in the HCPs to protect the Tribes if future litigation should arise.*

Response 42 The No Surprises policy applies specifically to an applicant who is issued an incidental take permit under Section 10 of the Endangered Species Act, and does not apply to Federal trust or treaty responsibilities. The Tribes have the option of participating in the HCPs as a signatory party. If the Tribes elect to sign the HCPs, then the Tribes directly receive the benefits of the HCPs. Even if a Tribe does not sign the HCPs, the Tribes nevertheless receive indirect benefits as a result of the commitments made by NMFS.

To provide some level of assurance to the Tribes on hatchery production and harvest issues in the near future, the signatory parties revised several aspects of the Hatchery Compensation Plan in the 2002 HCPs. First, the parties detailed the initial production levels that must be obtained to meet the no net impact standard for each project. Second, the parties agreed that hatchery production commitments, except for original inundation mitigation, shall be adjusted in 2013 (2018 for the Wells Project) and every 10 years thereafter to achieve and maintain no net impact. Thus, production levels, including those initially specified in the HCPs, shall be stable for 10-year intervals. This change was made to both provide greater assurances to the Tribes with respect to production levels (and harvest opportunities), and to allow sufficient amounts of time to pass (approximately 2 to 3 generations of fish) to assess the effects of previous changes to the hatchery programs.

NMFS believes that this level of assurance is roughly equivalent to the assurances provided to the applicants in the revised HCPs (i.e., that NMFS may withdraw from the agreements and revoke the permits after 2013 for the Chelan County PUD projects and 2018 for Douglas County PUD's Wells Project) if the stocks are not rebuilding and the projects are a significant factor in the failure to rebuild. Provisions were also included to indicate that the HCPs were not intended to create jurisdiction in any court (see HCP Section 11.3 [Dispute Resolution, No Intent to Create Jurisdiction]) nor in any way "abridge, limit, diminish, abrogate, adjudicate, or resolve any Indian

right reserved or protected in any treaty, executive order, statute or court decree" (Section 12.11 [Miscellaneous, Indian Tribal Treaty or Reserved Rights]), that the HCPs do not change the jurisdiction of the court in U.S. vs. Oregon, 302 F. Supp. 899 (D. OR 1969) or the parties' positions therein (Section 12.13 [Miscellaneous, No Precedent/Compromise of Disputed Claims]), and that the HCPs are not intended to establish a precedent or be interpreted as the position of any party in any proceeding not dealing specifically with the terms of this agreement (Section 12.12).

Comment 43 *Several commenters questioned the appropriateness and legality of including a No Surprises policy in the HCPs, suggesting that such assurances are inappropriate for HCPs of this type, covering facilities on a public waterway that are inextricably interconnected with other facilities and activities not covered by the HCPs, all of which affect the anadromous fish populations at issue.*

Response 43 In response to the concerns expressed in comments on the DEIS, the withdrawal and termination provisions contained in the HCPs supercede application of the No Surprises policy. In addition, Section 2 (Termination under Wells and Withdrawal from Agreement for Rocky Reach and Rock Island) of the HCPs now define circumstances under which NMFS may withdraw from the agreement and revoke the permits after 2013 for the Rocky Reach and Rock Island projects and after 2018 for the Wells Project, should no net impact not be achieved or the stocks fail to rebuild (see Section 2 of the HCPs).

The HCP handbook (USFWS and NMFS 1996) states that "[t]he Section 10 process is an opportunity to provide species protection and habitat conservation within the context of non-Federal development and land and water use activities … allowing economic development that will not appreciably reduce the likelihood of the survival and recovery of the species in the wild." Therefore, an HCP can be proposed where a Federal agency is involved in a cooperative planning effort in which both Federal and private lands are addressed under a single HCP but the Federal agency is not the applicant or the primary partner in the plan. For the Wells, Rocky Reach, and Rock Island HCPs, the PUDs are the applicants and project owners.

The No Surprises policy applies to the HCPs for utility-owned dams, rather than the Columbia River. The actions that would be implemented under the HCPs can be implemented independently of actions that occur at other Columbia River dams, hatcheries, or tributary areas. The permits granted with the implementation of the HCPs would cover the incidental take of listed species as a result of project operations, including direct, indirect, and delayed effects wherever they occur. The No Surprises policy applies to the mitigation for that take and not to the overall condition of the resource, or the other factors that can affect the recovery process.

Tribal Issues – Not in Agreement with HCPs

Comment 44 *Several commenters requested that the FEIS clearly indicate that although the Tribes and other resource agencies were involved in the HCP development, it should not be inferred that they agree with the current HCP provisions. The Tribal comments specifically stated that they do not agree with the provisions of the HCPs, because the Tribes have reserved the right to accept the HCPs only if all outstanding issues have been resolved. In addition, the hatchery compensation component of the HCPs is not the only HCP issue that concerns the Tribes. Several commenters indicated that the NEPA review process should be halted until all the HCP issues are resolved to the satisfaction of all the parties involved in the process.*

Response 44 Between September 2001 and March 2002, the parties that developed the 1998 HCPs (including the Tribes) began a round of intensive negotiations to resolve outstanding issues, including those specifically raised from DEIS public comments. A number of additions and revisions were made to the HCPs to address all Tribal concerns brought to the table. All of the negotiating entities (NMFS, USFWS, WDFW, Colville, Chelan and Douglas County PUDs, and Douglas County PUD's power purchasers) (with the exception of the Yakama and Umatilla Tribes and American Rivers) have signed the revised HCPs, signifying that these issues were resolved to their mutual satisfaction. It is NMFS's understanding at this time that the Yakama and Umatilla Tribes have decided not to sign and that American Rivers is still considering whether or not to sign the revised HCPs.

USFWS and NMFS (the Services) encourage all HCP applicants to invite and include other Federal and State agencies who can utilize their existing authorities, expertise, or lands in support of the HCP development and implementation process. Furthermore, the Services will consider whether the proposed HCPs might affect Tribal rights to trust and treaty resources. After careful consideration of the Tribes' concerns, the Services will clearly state the rationale for the recommended final decision and explain how the decision relates to the Federal Government's trust responsibilities. In light of this obligation, it was important that during the planning process, the Services identified and evaluated any anticipated effects of a proposed HCP upon Indian treaty and trust resources.

The EIS review process fulfills NMFS's NEPA compliance obligations as required for HCPs. Using the NEPA FEIS and biological opinion that will be prepared for the HCPs, NMFS will evaluate whether the HCPs satisfy provisions of Section 10 of the Endangered Species Act. Although NMFS would prefer that all parties involved in the HCP negotiation process sign the HCPs and participate in their implementation through the HCP committees, there is no Section 10 requirement that all the resource managers sign the HCPs.

Comment 45 *The DEIS does not mention the Yakama Nation's effort to resolve HCP issues of importance to the Yakama Nation with NMFS.*

Response 45 Prior to issuing the DEIS, NMFS staff had many discussions with staff of the Yakama Tribe and the other Joint Fisheries Parties to better understand and attempt to resolve remaining issues in the HCPs. Since the issuance of the DEIS, NMFS has continued to work with the original parties that developed the HCPs to resolve these issues, as well as additional issues identified in DEIS public comments. This effort culminated in the revised HCPs, which were provided to all potential signatory parties in March of 2002 for their consideration and signature. NMFS believes that the revised HCPs satisfactorily resolve the important issues raised in DEIS public comments or through continued discussions with staff representing the Joint Fisheries Parties. NMFS is fully aware of its trust relationship with the affected Tribes and is committed to working with these entities to protect anadromous fish resources under either action alternative.

Comment 46 *Tribal biologists requested dual complementing components for the no net impact statement that included a fish passage efficiency standard.*

Response 46 The HCP survival standards and Survival Standard Decision Matrix contained in the revised HCPs (see Figure 2-4 of the FEIS) represent a process for measuring the survival of adults and juveniles passing the dams and projects to the greatest extent that available technology allows (see HCP definitions of survival standards). Fish passage efficiency, typically defined as the proportion of juvenile fish passing a project using a non-turbine passage route, is at best an indirect measure of juvenile survival. Intuitively, increasing fish passage efficiency (by

increasing spill for example) should increase juvenile survival rates by reducing the proportion of juveniles passing through turbines—which is often the route of passage having the highest mortality rates. However, many other factors must be considered: high rates of spill might result in (1) gas bubble disease in juvenile and adult anadromous or resident fish, (2) tailrace conditions that decrease juvenile survival and delay adult passage, and (3) increased rates of fallback for adults. Thus, while fish passage efficiencies might be useful in assessing the potential benefits of alternative project operations on juvenile migrants, NMFS believes that the survival standards are the most appropriate for measuring whether or not the no net impact standards are being achieved. Fish passage efficiency estimates were used in the revised Rocky Reach HCP to adjust and set fish spill for the 2004, 2005, and 2006 migrations (see Section 5.4.1.a. [Passage Survival Plan Phase I Plan to Achieve Survival Standards, Juvenile Measures, Adjustment Period] of the Rocky Reach HCP [2002]).

Section 7 Consultation and Endangered Species Act-Related Questions

Comment 47 *Several commenters suggested that Section 7 consultation and relicensing procedures (where appropriate) should not be initiated until the HCP process has reached a satisfactory conclusion. Some concern was also expressed that the "conditional implementation" of the HCPs is resulting in the illegal taking of listed species because there is no Section 7 biological opinion for this action. Full mitigation for both listed and unlisted species has not been provided. Therefore, the HCPs will continue the taking of the species and lead toward their extinction.*

Response 47 Under the FEIS process, different alternatives can be selected for each of the three Mid-Columbia River hydroelectric projects. As a result, the relicensing process for Rocky Reach Dam is continuing on a parallel course, pending the outcome of the HCP. If Alternative 2 is selected for Rocky Reach Dam, Section 7 consultation between NMFS, USFWS, and FERC will satisfy the Endangered Species Act requirements of the FERC relicensing process. Outside relicensing, Section 7 consultations have occurred as a result of Federal actions at the Wells and Rocky Reach projects. Biological opinions for the Wells (NMFS 2000b) and Rocky Reach (NMFS 2002a) projects have been completed, but the biological opinion for the Wells Project has expired. No formal consultation on the Rock Island Project is occurring at this time. Although both Section 7 and Section 10 consultations attempt to minimize or mitigate for take associated with a particular activity, there is no expectation that take will not occur.

Both the Wells and the Rock Island projects are providing full hatchery mitigation for their project impacts as provided under the terms of their respective long-term settlement agreements. These agreements include hatchery mitigation based on an estimated 14 percent fish passage mortality. Because the HCPs permit a maximum of 7 percent mitigation through hatchery production, the hatchery production under Alternative 3 would be decreased compared to existing conditions. However, the revised HCPs allow for greater than 7 percent hatchery mitigation until 2013. Refer to Table 4-1 of the FEIS for specific hatchery production levels under Alternative 3. Under the HCPs, Rock Island hatchery mitigation will continue as part of the Rocky Reach mitigation plan through 2013. Hatchery mitigation for the Wells Project would be adjusted based on survival study results to reflect actual survival for yearling chinook salmon and steelhead and will remain at a full 7 percent for subyearling chinook and sockeye salmon.

NMFS has identified that Alternative 3 is the preferred alternative. Assuming that the HCP meets Section 7 consultation requirements for listed anadromous fish, NMFS would issue the incidental take permits, and FERC would amend the project licenses accordingly. Any HCP-related effects on listed bull trout, bald eagles, and Ute ladies' tresses would be addressed through Section 7 consultations with USFWS. Regardless of the selected action alternative, a biological opinion

supporting either an incidental take statement to authorize any incidental take by the Federal action agency (Section 7) or an incidental take permit that authorizes any incidental take by the Section 10 permittee would be required. See FEIS Section 1.5.2, Overview of Federal Requirements for Species Conservation that explain the PUDs' and FERC's roles and responsibilities in the two permitting processes.

Other Species

Comment 48 *Several commenters requested that lamprey, sturgeon and bull trout be included as Plan species in the HCPs. They also indicated that the FEIS did not give adequate consideration to these species, or detail how one alternative might be better than another for protecting these species.*

Response 48 The decision to include or exclude any species for an HCP is an applicant decision, and there are no provisions in the Endangered Species Act that require that all species affected by an action be included in an HCP. Although NMFS and USFWS (the Services) typically suggest that all listed species that could be subject to a take be included in an HCP, this is not required. Although these species are not included as Plan species, they were discussed and their needs taken into consideration when developing the HCPs. USFWS participated in the development of the HCPs and evaluated the HCPs to ensure that the HCPs posed no obvious problems for the needs of bull trout. The HCPs' effects on bull trout will also be evaluated in a separate Section 7 consultation. The protection of these species is expected to be the same for both action alternatives.

There are limited data concerning the status of lamprey, sturgeon, and bull trout within the project area, including the potential impacts of the Mid-Columbia River projects on these species. Although the FEIS acknowledges that these species could be affected by the projects, there is no known quantitative data available. This lack of information is one reason that the species were not included as Plan species in the HCPs, because no performance standards could be developed. However, protection and mitigation measures for lamprey, sturgeon, and bull trout are expected to occur through FERC relicensing procedures. The PUDs could request an incidental take permit for bull trout from the USFWS once sufficient information is developed.

The potential measures that could be implemented at the projects to improve fish passage are limited. Alternative 2 evaluates alternative protective measures at the projects, including elevated spill levels. It is recognized that full implementation of Alternative 2 measures is less likely for non-listed Plan species and could be substantially delayed for all species through litigation or FERC's relicensing and rehearing processes. Under Alternative 3, the measures would be implemented immediately and should improve the juvenile fish passage conditions for downstream migrating Plan and non-Plan species alike. Other potential impacts to resident fish are expected to be similar for both action alternatives, and are not a significant factor in determining the preferred alternative.

Another difference between the action alternatives with regard to non-Permit or non-Plan species is the provision of a Tributary Conservation Plan under Alternative 3. The goal of the tributary committees is to select and fund ecologically sound tributary improvement projects with the Tributary Enhancement Fund. These projects will be selected by the tributary committees and would focus on Plan species, although the potential benefits and impacts to other species would be considered in any decision. Any project that would directly affect the tributary streams (e.g., culvert removal) would require environmental permits, which would provide another layer of protection for non-Plan species. The Tributary Plan is expected to benefit all native aquatic species that occur in the tributaries. Alternative 2 does not include PUD funding of tributary habitat projects.

Neither action alternative directly addresses lamprey, sturgeon, or bull trout. Under either alternative, the protection of these species would occur through relicensing and other statutes and laws. As a listed species, however, bull trout would be addressed through Section 7 consultation under both of the action alternatives at relicensing or at the time of a Federal action, unless they were addressed through a separate incidental take permit under Section 10.

Information about these species has been added to FEIS Section 3.2.8, Species of Concern. Additional discussions of the potential benefits or impacts to lamprey and sturgeon have also been added to Chapter 4 of the FEIS for each alternative. The HCPs and the FEIS identify specific project modifications and operations that would initially be implemented through 2006 at Rocky Reach to improve fish passage survival. Under Alternative 2, FERC (at the request of the licensees) would select the bypass options or project operations to protect unlisted species at the projects. Under Alternative 3, the HCPs address Plan species, but it is reasonable to assume that they would consider the effects of actions on other species. Note that the exact changes to long-term project operations or modifications under either action alternative cannot be specifically defined, nor the specific habitat improvement projects that might be selected by the tributary committees under Alternative 3. Therefore, the environmental consequences analysis for these species is more qualitative.

Relicensing Issues

Comment 49 *The stakeholders should be allowed to participate in the relicensing of the Rocky Reach Project without the constraint of the HCPs, and the HCPs should match the existing terms of the FERC licenses for the projects. The implementation of Alternative 3 would predetermine the extent of the recovery measures at relicensing and impose conditions on subsequent licenses many years before the relicensing process. Others questioned the 50-year term of the HCPs and whether the terms should be linked to the relicensing schedule.*

Response 49 The 50-year term of the HCPs was selected to coincide to the extent possible with a typical 30- to 50-year term of a FERC license. Chelan County PUD is currently proceeding with the relicensing of Rocky Reach Dam, and the terms of the HCP and the FERC license would likely be similar. The Wells and Rock Island licenses would expire prior to the 50-year term of the HCPs. When this occurs, the PUDs would be required to proceed with the relicensing process. Although the HCPs would form the basis for mitigation measures for anadromous fish during this process, FERC has an obligation to independently ensure that adequate protection of all natural resources is provided in the license terms. Parties that sign the HCPs also commit to supporting the PUDs in the relicensing process by not recommending mitigation measures that are different from those outlined in the HCPs. However, non-signatory parties can petition FERC to have specific measures included in the license terms. Signatory parties can also petition FERC to include license terms for non-Plan species, which might also coincidentally benefit Plan species. In addition, NMFS can terminate the agreements and revoke the permits in 2013 for Rocky Reach and Rock Island and in 2018 for Wells, if the HCPs are not leading to the recovery of the species, or if the PUDs fail to meet or maintain no net impact. At this time, NMFS could seek drawdown, dam removal, or non-power operations or actions for achievement of no net impact. The HCPs would not affect any stakeholder decision to be involved in the Rocky Reach relicensing effort, although the HCPs define the positions that the signatory parties would consider in any relicensing effort.

Other time frames may not be as effective over the long term because of the significant time and effort required to negotiate and consult with the various parties on successive HCPs. For example, these HCPs have been discussed and negotiated since 1993. During this negotiation

process, the HCPs were only conditionally implemented, and this was a voluntary action by the proponents. At a minimum, Alternative 2 would match the terms of the FERC licenses because Section 7 consultation would be required for the FERC action to relicense the projects. FERC has held that absent a Federal action before relicensing, a Section 7 consultation would not commence until each project was relicensed. While Rocky Reach relicensing is commencing, relicensing for Wells is a few years off and Rock Island will not expire until 2029. However, this is mitigated at the Rocky Reach and Wells projects, as their effects on salmon and steelhead are currently addressed through existing biological opinions (though the biological opinion for Wells has expired).

The purpose of Section 10 provisions of the Endangered Species Act is to provide an alternate avenue for addressing Endangered Species Act compliance while allowing some level of certainty to the proponent. If Alternative 3 were restricted to the same time periods for Federal Power Act processes and Endangered Species Act consultations as Alternative 2, there would be little incentive to apply for a Section 10 permit. The HCP process is extremely time-consuming and expensive, and should provide a correspondingly greater level of certainty and cover a longer time period than Section 7 consultation. Although the HCPs are all separate agreements, the intent is to provide a coordinated effort throughout the Mid-Columbia River reach to address recovery issues for the Plan species. Therefore, coordinating the time frames of the HCPs is likely to be more important to the recovery process than coordinating the HCPs to the FERC license schedule. This information has been added to FEIS Section 2.3.4.2, HCP Term.

Endangered Species Act compliance is only one aspect that should be considered during the FERC relicensing process. The action alternatives cover a limited number of species that are or could be affected by the projects. Protection measures for other species would occur through relicensing under all the alternatives. As a Federal agency, FERC is bound by the responsibility to "adequately and equitably protect, mitigate damages to, and enhance, fish and wildlife (including related spawning grounds and habitat)" affected by the project (16 USC § 803(j)(1)). As such, FERC must weigh the opinions and recommendations of all of the resource agencies and stakeholders, as well as other interested parties. Non-signatory parties can raise any issue or concern during the relicensing process to document that the mitigation measures implemented as part of the HCP processes are not adequate to protect the species. The responsibilities of FERC to protect these resources would not be limited by the HCPs, and FERC would have an obligation to condition the license with appropriate mitigation measures. Before adopting the HCPs into the project licenses, FERC would determine if the HCP provisions fulfill their responsibilities, and that additional protection measures were not necessary. FERC is intending to use the FEIS to fulfill NEPA requirements and would consider all comments on the FEIS in their decision.

If salmon and steelhead populations dramatically decline in the future and the projects are determined to be a significant cause of the decline, NMFS would likely pursue significant changes to the projects (e.g., drawdown, dam removal, or non-power operations). NMFS could terminate the agreements and revoke the permits to pursue these types of options in 2013 (2018 for the Wells Project). Overall, the HCPs only affect the mitigation at three of the nine dams on the Columbia River that impact the listed species. Therefore, adequate opportunities are available to protect the species during this initial period, if the species are declining.

Other Existing Agreements

Comment 50 *Several commenters requested clarification on how the action alternatives would affect the ongoing Mid-Columbia Proceedings and agreements that are under jurisdiction of a FERC administrative law judge. There were also some concerns about how they would affect the ability*

of the Joint Fisheries Parties to regulate project operations to protect water quality and aquatic species. Others expressed concern that under Alternative 3, the Joint Fisheries Parties have the burden of proof in the dispute resolution process, while under Alternative 2 this responsibility is shared equally with the PUDs.

Response 50 FEIS Section 2.3.2, Alternative 1 (No-Action) provides detailed descriptions of the current operational requirements of the PUDs under the existing settlement agreements, which are the basis for Alternative 1. Long-term juvenile protection measures have not been established for Rocky Reach. These measures are the subject of a pending proceeding at FERC known as the Mid-Columbia Proceeding. The last interim stipulation to define the project's obligations expired in 1997. Until either a new stipulation is signed or FERC establishes license requirements, Chelan County PUD has agreed to and is currently conditionally implementing many of the agreed-upon provisions of the revised 2002 Rocky Reach HCP (Alternative 3). The Mid-Columbia Coordinating Committee has no jurisdiction absent a stipulation between the parties. The revised 2002 HCP will be presented to FERC as an offer to settle the Rocky Reach portion of the Mid-Columbia Proceeding, including a request that FERC incorporate the HCP as a special license article. The Rock Island and Wells dams have long-term settlement agreements in place, and the respective PUDs have agreed to conditionally implement many of the measures included in the revised 2002 HCPs (Alternative 3).

All three HCPs (Alternative 3) require the signatory parties to work together in addressing water quality issues. Chelan and Douglas County PUDs are also working directly with Ecology to resolve water quality issues. Alternatives 1 and 2 do not address water quality as a specific conservation measure to be implemented. However, analysis of possible spill levels in Alternative 2 does recognize the 120 percent total dissolved gas waiver granted each year at the Columbia River hydroelectric projects for the purpose of improving juvenile salmon and steelhead survival past the dams. (See response to Comment #39 for a discussion of how the burden of proof comments were addressed in the 2002 HCPs.)

FEIS Section 2.3.2, Alternative 1 (No-Action) indicates that the provisions of the existing settlement agreements would also apply under Alternative 2 for unlisted species. However, because the listed species have continued to decline under the framework of these provisions, NMFS would likely require that additional measures be implemented to protect and lead to the recovery of the listed species. In addition to potentially requiring additional measures to improve fish passage conditions at the projects, NMFS is expected to require changes to the hatchery compensation portions of the settlement agreements for spring-run chinook salmon and steelhead. These changes are expected to be similar to those that would occur under Alternative 3. Although additional measures might be required to protect and lead to the recovery of listed species under both action alternatives, the Services would likely continue to use the Mid-Columbia Proceeding's Mid-Columbia Coordinating Committee and the Wells Settlement Agreement's Coordinating Committee processes to solicit input for all major decisions under Alternative 2 (NMFS 2000b, 2002a).

NEPA/EIS-Related Questions

Comment 51 *Several commenters indicated that previous scoping comments were not specifically addressed, and the DEIS did not take a hard look at the environmental information and consequences of each alternative (particularly over the long term). Others requested changes to the Purpose and Needs section of the EIS to give greater importance to the recovery of the listed species than to the generation of electricity.*

Response 51 The purpose of scoping was to obtain information that focused the NEPA analysis on significant issues. Scoping is defined by NEPA regulations (40 CFR 1501.7) as "an early and open process for determining the scope of issues related to a proposed action." All comments provided during this process were considered in identifying the issues associated with the proposed action (Parametrix 1999b). Generally, letters received during scoping do not receive response letters from the lead agency unless there is a specific request in the comment letter.

Protection of listed species and compliance with the Endangered Species Act is included in the Purpose and Need section (see FEIS Section 1.3, Purpose and Need). The purpose includes ensuring stable power supplies and pricing for the utility's customers. An additional statement was added to FEIS Section 1.3, Purpose and Need regarding the need to operate for power production while protecting fish.

As a result of the DEIS public review process and subsequent 2002 HCP negotiations, the FEIS was revised to include additional mitigation measures raised during the DEIS public review process for the action alternatives. These two alternatives include a variety of mitigation measures for comparison. In addition, the FEIS notes that the timing and certainty of implementation varies between the two action alternatives. Under Alternative 3, the mitigation measures will be implemented immediately, while under Alternative 2, they might be implemented after several or many years have elapsed, depending upon the likelihood and length of litigation and FERC's decision and appeal process. Alternative 3 also immediately affords the same protection for unlisted as listed Plan species, which is less likely to occur under Alternative 2 for the same reasons as those mentioned above for listed Plan species.

The FEIS also includes a review of the Quantitative Analysis Report (QAR) (see Chapter 5 of the FEIS and Appendix E) that describes the long-term risks associated with Alternative 3 relative to the recovery of the listed species. Off-site mitigation in the form of PUD funding of tributary enhancement projects is not included under Alternative 2 (see FEIS Section 2.6.6.2, Alternative 2). Hatchery production under Alternative 2 is addressed through the existing settlement agreements or during relicensing, although specific changes to the allowable compensation level could result from the Section 7 consultation. Detailed information about the effects of the alternatives on anadromous fish is presented in FEIS Sections 4.2.2, Alternative 2 and 4.2.3, Alternative 3.

Quantitative Analysis Report

Comment 52 *The Quantitative Analysis Report (QAR) states that additional survival improvements beyond those projected for the draft HCP actions would be necessary to achieve extinction risk/recovery criteria. This information should be analyzed in the FEIS, as well as the potential for enforcing the necessary changes in the Lower Columbia River.*

Response 52 The purpose of the FEIS is to inform the public and decision-makers about the environmental effects of a reasonable set of alternatives. Final determination of whether the selected alternative meets the requirements of the Endangered Species Act or includes all of the necessary mitigation measures for species protection will occur with the issuance of a biological opinion. Under Alternative 2, NMFS would issue a biological opinion to FERC. Under Alternative 3, NMFS would issue a biological opinion to itself (in this instance NMFS would be the action agency proposing to issue a Section 10 permit to the PUDs) and make the finding required by Section 10 of the Endangered Species Act.

In either case, NMFS must ultimately issue a biological opinion determining whether or not the proposed action is likely to jeopardize the continued existence of the listed species. Also in either case, a jeopardy determination would require NMFS to provide the action agency with a reasonable and prudent alternative that includes measures necessary to avoid jeopardizing the listed species. These recommendations may not necessarily be those specified in the HCPs. The determination of Federal Power Act compliance will occur after Section 7 consultation with FERC and the resulting relicensing or license amendment process conducted by FERC.

Section 7 of the Endangered Species Act requires all Federal agencies, in consultation with NMFS and USFWS (the Services), to ensure that any action "authorized, funded, or carried out" by any such agency "is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification" of critical habitat. Under a jeopardy determination, the Services can specify "reasonable and prudent" alternatives, although the alternatives should be consistent with the intended purpose of the action and economically and technologically feasible. Conversely, Section 10 states that an incidental take permit can be authorized if the activity will not "appreciably reduce the likelihood of the survival and recovery of the species in the wild", and includes the development of a mitigation program that minimizes and mitigates take "to the maximum extent practicable." In either case, there is no criteria to recover the species, only a requirement to not "reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild" (50 CFR § 402.02). As indicated in the FEIS, Alternative 2 could potentially provide more opportunities to protect the species because it allows for the reinitiation of consultation at any time if new information indicates that the existing protection measures are not adequately protecting the species. Under Alternative 3, the permits could not be revoked until 2013 (2018 for Wells Dam) and every 10 years thereafter. Nevertheless, the HCPs and permits may be modified by agreement of the parties, consistent with the revised HCPs. The HCPs incorporate NMFS regulations that provide for changes to a permit. However, the HCPs will be adaptively managed by the coordinating committees to take into consideration newly available information—paying special attention to the results of the required survival studies. The revised HCPs clarify how additional measures would be instituted should the results of these studies indicate that the pertinent survival metrics are not being attained. Thus, there is likely to be little, if any, difference between the two action alternatives with respect to the timely implementation of protective measures in response to newly available information.

Revisions to the FEIS discussing the potential shortfall of the HCP measures at reaching the necessary survival levels are found in Chapter 5 and Appendix E. However, the additional measures identified in the QAR consist of lower river survival improvements and a shift in recent climate/environmental conditions, neither of which is under the control or responsibility of the PUDs. The QAR also indicates that, even if the dams were removed, these additional survival improvements would also be needed. The shortfall is more of a system-wide concern than a Mid-Columbia River concern. Therefore, it is unlikely that Alternative 2 would be more protective of listed species than Alternative 3, given the available provisions under the Endangered Species Act. The cumulative effects analysis (Chapter 5) can only project reasonable foreseeable future actions, but cannot enforce those actions that are outside the project applicant's purview. Therefore, the survival improvements called for in the Federal Columbia River Power System biological opinion (NMFS 2000a) are assumed to be achievable.

Comment 53 *The Quantitative Analysis Report (QAR) has several shortcomings that should be addressed in the FEIS: (1) survival improvements would occur instantaneously, (2) the Priest Rapids Project would achieve a 95 percent survival standard, (3) adequate assessment of the hatchery supplementation program, and (4) assumed survival improvements at other hydroelectric projects that are currently not being met.*

Response 53 Because the QAR is a modeling exercise, there are various constraints and assumptions that are inherent in the process. Some of the assumptions that were necessary were that the survival improvements were instantaneous (survival study information suggests that Rock Island, Wells, and some species at Rocky Reach may already be meeting or exceeding the survival levels assumed in the QAR; see Chapter 3 of the FEIS), and that the Priest Rapids Project would also achieve the same 93 percent project survival which was modeled. Other assumptions were also used that may not either be known or reflect the latest information, but were the best information available at the time of the modeling process. Assuming that the survival improvements were met at other projects was also necessary to determine whether the extinction risks, or the ability to meet the interim recovery levels, were possible with alternatives that are being considered or implemented.

Due to long-term uncertainty associated with the effectiveness of hatchery supplementation, the QAR analyses did not incorporate continued supplementation as envisioned under the proposed HCPs. However, other HCP actions, such as dam passage survival and tributary habitat enhancements, were considered in the QAR analysis. In addition, the QAR also assumed that the survival improvements expected at the three dams and the tributary enhancements would occur instantaneously. However, it may take several years or, in some cases, a decade or more before the survival benefits of certain actions (e.g., habitat improvements) are fully realized.

Comment 54 *The FEIS must discuss that the Quantitative Analysis Report (QAR) indicates a substantial risk of extinction without supplementation. Removal of Mid-Columbia dams would help to increase survival, critical fish habitat, and productivity.*

Response 54 Under NMFS guidelines, hatchery production is explicitly not included in the assessment of long-term sustainability of a stock. However, for Upper Columbia River steelhead, the QAR included an assessment of the relative risks of extinction under alternative assumptions regarding the effectiveness of hatchery origin spawners. NMFS agrees that, in some instances, hatchery supplementation can play a separate and important role in addressing particular Endangered Species Act-listed stock recovery issues.

The FEIS and QAR address extinction risks that would result from removal of the Mid-Columbia dams. Chapter 5 of the FEIS was revised to say: "… the risk of extinction and the probability of reaching the interim recovery goals are dependent on the assumption of future environmental conditions and consequently, which part of the existing data set is used. Also, under the most conservative view of future environmental conditions (using the 1980 to 1994 brood year data set), even dam removal would not allow the achievement of acceptable risk of extinction or meeting the interim recovery goals."

Project Area

Comment 55 *Several commenters suggested that the project area should be enlarged to include both upstream and downstream hydroelectric projects.*

Response 55 The project area defined for this FEIS is based on (1) the regulatory framework necessary for analyzing project effects under the Endangered Species Act, (2) the location of the proposed action (fish protection measures), and (3) the project applicants' ability to control and/or affect the subject of the proposed action. The PUDs do not have the authority to control or affect fish protection measures beyond the project boundaries. The tributary programs of the HCPs extend beyond the project boundaries, but specific programs will not be implemented without the voluntary support of property owners. The upstream projects are Federal projects outside of the

control of Chelan and Douglas County PUDs. The downstream projects (Wanapum and Priest Rapids dams) are owned by Grant County PUD, which has elected to use the Section 7 consultation process to satisfy Endangered Species Act requirements. The Lower Columbia River projects are Federal projects also outside of the control of Chelan and Douglas County PUDs. However, the upstream and downstream hydroelectric projects are considered in the Quantitative Analysis Report (QAR) and in the FEIS's cumulative effects analysis for those actions that can be predicted to occur over the life of the project. See Chapter 5 of the FEIS.

Representative Survival Studies

Comment 56 *Several commenters identified the lack of specific information regarding how performance standards will be measured. Survival evaluations are needed for each migrant life stage of each Plan species. In addition, survival standards must not be presumed to be met until certified by the coordinating committees. The use of surrogate species for survival evaluations was also questioned as inappropriate.*

Response 56 The revised HCPs now include a Survival Standard Decision Matrix (see Figure 2-4 of the FEIS), which identifies the priorities of HCP survival metrics and indicates which phase determinations would be made, given a particular result of the different Phase I survival studies that could be conducted. The HCPs clearly indicate that survival evaluations are required for each Plan species. An important amendment was the addition of 93 percent juvenile project survival measurement. The HCPs also specify that the coordinating committees are responsible for determining the most appropriate standard to be measured for each Plan species, approving studies prior to implementation, establishing the protocol(s) and methodologies to determine whether or not the survival standards are being achieved, and determining whether or not the no net impact standard is being achieved (see Section 6.7 of the Wells HCP [Reservoir as Habitat and Water Quality, Authority], and Section 4.7 of the Rocky Reach and Rock Island HCPs [Coordinating Committee, Authority]). Other clarifications made in the revised HCPs pertaining to the performance standards include explicit criteria (and flexibility around those criteria) for coordinating committee determinations regarding whether or not a study is valid (meets standards for representative flow conditions and statistical accuracy) and the use of an average (arithmetic mean) based on the point estimates from 3 years of valid studies to be used as the metric for comparison against the pertinent survival standard (see Section 4.1.4 of Wells HCP [Passage Survival Plan, Survival Standards, Methodologies] and Section 5.2.3 of the Rocky Reach and Rock Island HCPs [Passage Survival Plan Implementation of the Survival Standards, Methodologies]).

Two exceptions to these conditions pertain to Permit species at the Wells Project. Based on high survival estimates (averaging 96.2 percent) from 3 years of studies at the Wells Project (2 years for steelhead and 1 year for spring-run chinook salmon), the signatory parties have agreed that the project has achieved the 93 percent juvenile project survival standard for these species. After considering the unique design of the Wells Project and its proven ability to efficiently pass juvenile salmon through the modified spill bays, the signatory parties have also agreed that the calculated juvenile dam passage survival of sockeye and subyearling chinook salmon is probably greater than 95 percent (see Section 3.1 of the Wells HCP [Survival Standards and Allocation of Responsibility for No Net Impact]).

Under the revised agreements, Phase III (Standards Achieved) can only be designated for a Plan species if studies conducted in accordance with the approved methodologies and criteria (see above) indicate that either the 91 percent combined adult and juvenile survival standard or the surrogate standard of 93 percent juvenile project survival is being achieved at the project for that

species. The signatory parties recognize that for some species (such as sockeye and subyearling chinook salmon) where measurement of juvenile dam passage survival and juvenile project survival is not yet possible, the juvenile dam passage survival standard will be calculated based on the best available information (including route-specific passage rate and mortality estimates) as determined by the coordinating committees. Unlike the measured standards, however, the calculated standard might utilize off-site information where site-specific information is lacking.

If, at any time during Phase III (Additional Juvenile Studies), the appropriate coordinating committee approves the use of new survival methodologies (to measure a higher-priority survival standard according to the Decision Matrix), the PUD will have 5 years to conduct the appropriate evaluations. Based on the results of these studies, the appropriate coordinating committee will reevaluate the phase determination for the pertinent species. If the coordinating committee agrees (based on the results of these studies) that the applicable standard is met, Phase III (Additional Juvenile Studies or Standard Achieved) status will remain. If the applicable standard is not being met, a Phase II determination would be made and the coordinating committee would determine what additional tools would be implemented to achieve the applicable survival standard.

The methodologies utilized to measure the pertinent survival standards would be similar for both action alternatives (see HCP supporting document on survival estimating), except that these studies would likely only be conducted for listed species under Alternative 2, but would be required for all Plan species under Alternative 3. In addition, for listed species, the use of the juvenile project survival standard as the primary method of ensuring compliance would also be common to both alternatives.

Some methods would provide adequate data for certain species or life stages, but may not be as well suited for other species for a variety of reasons (see HCP supporting document on survival estimating). However, decisions must be made based on the best available scientific data. The methods currently being used to assess project impacts are the best available methods, although they might not provide conclusive results for all species, life stages, or potential project impacts. The survival studies conducted at the PUD projects under Alternative 3 will include the best available techniques and protocols as agreed to by the HCP coordinating committees. These same techniques are expected to be included under Alternative 2 to assess mitigation requirements or performance. However, due to the considerable expense of conducting survival studies, the limited availability of test fish (particularly for depressed stocks), and the limitations of the assessment techniques, it may not be feasible to acquire survival data for each species. Therefore, it may be necessary to use data from surrogate species, populations, or life stages to estimate survival for those species or life stages that cannot be effectively evaluated at the present time. For example, instead of using Endangered Species Act-listed spring-run chinook salmon and steelhead, hatchery or mixed-stock run-of-the-river fish would likely be used in survival evaluations.

Due to the uncertainties associated with any survival estimation technique, there are frequent disputes over the various aspects of the studies or the interpretation of the results. These disputes will likely continue under either action alternative. However, because criteria and methodologies have been substantively agreed upon by the signatory parties in the revised HCPs, the likelihood and magnitude of these disputes is expected to be less under Alternative 3 than under Alternative 2.

Survival Study Uncertainties

Comment 57 *There is a lack of commitment to conduct survival studies on any Plan species, except for those that are also listed. In addition, the practicality of marking large numbers of Plan or Permit species for either Phase I or II evaluation or Phase III monitoring efforts is questionable due to the scarcity of test animals. These limitations could affect the ability to verify meeting the standards. It is also unclear if all the Plan species could be evaluated in 3 years.*

Response 57 Under Alternative 3, the methods used to assess survival rates for each Plan species at the projects would be determined by the coordinating committees in accordance with the requirements of the revised agreements and in consideration of the supporting documents appended to the agreements. The coordinating committees are responsible for determining the most appropriate methodology for each of the Plan species, recognizing that one methodology may not be suitable or appropriate for all the species or life stages. Therefore, survival studies will be conducted for all the Plan species, except where no appropriate methodology exists (see Survival Standard Decision Matrix, Figure 2-4 of the FEIS).

The revised HCPs acknowledge that limitations on the number of fish needed to make accurate survival estimates are an important consideration in determining the most appropriate methodology for assessing the pertinent survival standard (see HCP supporting document on survival estimating). Some methodologies (radio or acoustic tags, for example) may be able to generate sufficiently accurate estimates with relatively small numbers of fish, but these tags have limited longevity, potentially limiting their ability to assess indirect and delayed mortality. In comparison, PIT tags have no longevity limitations, and are therefore more likely to completely assess indirect and delayed effects. However, using this methodology requires tens or hundreds of thousands of tagged fish to generate sufficiently accurate survival estimates. The coordinating committees will be responsible for assessing the available methodologies and determining which can best be used to assess the pertinent survival standard for each Plan species. The revised HCPs also require the coordinating committees to facilitate the availability of test fish for studies, which may include the rearing of additional hatchery fish (e.g., Section 4.10 of the Rocky Reach and Rocky Island HCPs [Coordinating Committee, Methodologies/Test Fish]).

The HCPs contain specific criteria for determining the statistical significance of survival test data. The point estimate should have a standard error of no more than ±2.5 percent (i.e., 5 percent error) at the 95 percent confidence level. If these criteria are not met, the study results would be rejected and an additional year of testing would be required. However, under conditions specified in the HCP and with unanimous agreement, the coordinating committees could accept the results of a less precise survival study for inclusion in the 3-year average if the standard error does not exceed ±3.5 percent. If the arithmetic mean (average) of the 3 years of studies is no more than 0.5 percent below the survival standard, the coordinating committees may decide whether an additional year of study is appropriate before making the final phase determination.

The HCPs state that point estimates from at least 3 years of valid studies would be averaged and compared against the pertinent survival standard to determine the phase designation for a Plan species. This does not necessarily require that the testing be conducted in 3 consecutive years or that all of the studies for each Plan species be conducted simultaneously. The phase determination would be identified for each Plan species individually. As such, the determination for one species does not necessarily affect the determination of any other species, unless the coordinating committee agrees that the survival rate for a monitored species likely represents the survival rate for a species that cannot be monitored effectively and accurately.

Under Alternative 3, to receive a Phase III (Standard Achieved) designation for a Plan species by the coordinating committees, the PUDs must achieve the 91 percent combined adult and juvenile survival standard or its surrogate, the 93 percent juvenile project survival standard. The measurement of these standards include direct, indirect, and delayed mortality wherever it may occur and can be measured (as it relates to each project) given the available mark-recapture technology for each Plan species. Under Alternative 2, only the listed species would likely receive this level of protection.

Adult Survival

Comment 58 *Adult passage and survival standards have not been quantitatively measured, and should be addressed in the EIS. A more thorough discussion of adult protection measures should be provided in the EIS analysis, as well as the effects of project operations (e.g., power peaking). The EIS should include recent results from adult radio telemetry studies.*

Response 58 The difficulties of quantifying adult mortality related to project operations are the same for all alternatives. These difficulties relate to the inherent inaccuracies in the available monitoring methods, and the inability to differentiate the cumulative impacts to adults from passing downstream projects with the direct impacts at any one particular upstream project. Furthermore, there is presently no available technology allowing the parties to differentiate hydro-related mortality from natural adult losses, which are known to occur in even the most pristine river systems. Recognizing these difficulties, and based on regional information, the signatory parties agree that adult fish survival is estimated to be 98 to 100 percent at each project. Analysis conducted as part of the 2000 Federal Columbia River Power System biological opinion (NMFS 2000a) and the Rocky Reach biological opinion (NMFS 2002a) provide additional evidence that total mortality rates are likely no more than 2.4 percent for spring-run chinook salmon and 3.2 percent for steelhead. Taking into account natural mortality, which undoubtedly occurs, it is likely that the 2 percent adult mortality resulting from project-related effects is currently being attained, at least for the listed species for which estimates are available. The assumed unavoidable mortality of adults is compensated through funding of the Plan Species Account.

The adult passage plans are similar to those required at downstream Federal projects on the Columbia River. The passage times at the projects covered by the HCPs are within the ranges of those observed at other mainstem hydroelectric projects on the Columbia and Snake Rivers. At other mainstem projects, NMFS has determined that, while delays may occur in passing mainstem projects, adults likely migrate faster in the pools than they did in the free-flowing river (NMFS 2000a). Because these project effects tend to offset each other, the potential effects of project passage delays are likely small and would be equivalent for either action alternative.

The difficulties of interpreting tagging results for adult fish are the primary reason that specific performance standards have not been identified in the HCPs for adult passage. There are a number of reasons for fish to delay passing a project that are not related to passage conditions. For example, fish may mistakenly migrate past their natal tributary stream or hatchery, and as a result, might be more reluctant to pass a project than those that are destined for upstream spawning areas or hatcheries. Passage delays might also be affected by life-history characteristics of Plan species, fish maturation, physical conditions related to the entire migration area, or the tagging and handling process. Note that there are little or no data that accurately estimate the effects of passage delays on spawning success. The estimates of delay provided in the FEIS were included to indicate overall fishway passage conditions and reflect median passage times**.**

The HCPs require the PUDs to use their best efforts to operate and maintain the adult fishways in accordance with approved Detailed Fishway Operation Plan criteria (or equivalently protective criteria in the case of Wells Dam), and any subsequent revisions to these criteria, which are a component of the provisions in existing settlement agreements and project licenses. These criteria are therefore likely to be part of the requirements under Alternative 2, at least initially. If the criteria are changed as a result of Section 7 consultation under Alternative 2, the criteria could result in a preference for listed species over unlisted species. However, until accurate estimates of impacts to adult fish can be quantified and related to specific project operations, there is no basis for altering the current ladder operating criteria for adult fishway operations at the projects.

In addition to meeting the various adult fishladder operating criteria under Alternative 3, the PUDs also have the 91 percent combined adult and juvenile project survival standard, which includes adults. Therefore, as monitoring methods improve over time, the results would be used to further refine the estimates of adult mortality that would be included in measuring survival against the performance standards. Not achieving the performance standards for all Plan species requires the PUDs to continue to implement tools in an effort to meet the standards.

The Federal Columbia River Power System biological opinion (NMFS 2000a) concluded that, although power peaking can affect spawning adults, egg incubation, and fry rearing stages, power peaking alone does not have a significant adverse effect on migrating salmon.

Comment 59 *The DEIS should include an analysis of adult losses, examine the adequacy of the adult passage plans, and address mitigation for adult losses under the alternatives.*

Response 59 See response to the previous comment.

Evolutionarily Significant Unit Issues

Comment 60 *What is the standard by which the status of the Evolutionarily Significant Unit is measured?*

Response 60 See answer to Comments #8 and #9.

Comment 61 *The geographic place and biological terms that would be used to measure progress toward recovery of the chinook salmon Evolutionarily Significant Units should be described.*

Response 61 See answer to Comment #10.

Conditional HCP Implementation

Comment 62 *Several commenters questioned various aspects of the conditional implementation of the HCPs, including (1) the lack of a signed implementation agreement, (2) the effects that this has on resolving outstanding issues at the projects, (3) whether the steady progress criteria applies during the conditional period, (4) how Chelan County PUD can continue to develop their juvenile bypass system without a signed agreement, and (5) why the PUDs can avoid meeting requirements in the existing settlement agreements. Others questioned how the PUDs could continue to "take" listed species without a Section 7 biological opinion.*

Response 62 Under the original HPCs, the PUDs conditionally implemented the HCPs without a signed implementation agreement and the parties agreed that the monitoring and evaluation components of the HCPs would not begin until the HCPs were signed and Phase I was completed. The primary reason for conditionally implementing the HCPs was because the time frame for Phase I

(1998 through 2003) had already begun, and might not have changed even with delays in approving the HCPs. Therefore, the PUDs would still need to demonstrate that they have achieved the HCP performance standards by the end of Phase I. Also during Phase I, the PUDs were allowed to use any tool or combination of tools in the pursuit of meeting the survival standards.

Discussions amongst the original HCP signatory parties regarding the resolution of outstanding issues nearly broke down in 2001, after the DEIS was released. Chelan County PUD chose, citing emergency conditions in the western energy grid and high costs of replacement energy, to reduce or eliminate spill at their Rock Island and Rocky Reach projects, respectively, to pre-HCP levels. While this almost certainly resulted in a negative impact to Plan species in 2001, Chelan County PUD's actions ultimately provided pressure on the signatory parties (including Chelan County PUD) to resolve outstanding HCP implementation issues as well as issues brought to NMFS's attention through public comments on the DEIS. The signatory parties to the revised HCPs believe that these issues have now been resolved to the mutual satisfaction of all the parties, and will likely provide greater benefits to all Plan species in a shorter period of time than would an Endangered Species Act Section 7 consultation. This is because under Alternative 3, the mitigation measures will be implemented immediately for all Plan species, while under Alternative 2, they might be implemented after several or many years have elapsed, depending upon the likelihood and length of litigation and FERC's decision and appeal process.

All references to "steady progress" have been removed from the revised HCPs. These documents now clearly indicate the signatory parties' expectation that the pertinent survival standards for all Plan species will be met by 2013. Should survival studies indicate that the pertinent survival standard is not being met for one or more Plan species at the end of Phase I, the coordinating committees would determine what additional measures (or tools) would be implemented to meet those standards (Phase II). Additional survival studies would be implemented to ensure that the protective measures were now achieving the pertinent survival standard.

Although the PUDs have voluntarily agreed to conditionally implement the provisions of the HCPs as a good faith effort, this does not minimize or replace their responsibilities established through their existing licenses and agreements, or those required under relicensing. Providing NMFS with Section 10 applications does not allow FERC (and their designated non-Federal representatives—the PUDs) to avoid compliance with the Endangered Species Act through Section 7 consultations. Since the DEIS was released, both the Wells and Rocky Reach projects have undergone Endangered Species Act Section 7 consultation for interim operations (and the construction of a juvenile bypass system at Rocky Reach Dam). Both Section 7 and Section 10 consultations attempt to minimize or mitigate for take associated with a particular activity; however, there is no expectation that take will not occur.

The Rocky Reach Fourth Revised Interim Stipulation states that the main goal is to develop a safe bypass system (less than 2 percent mortality), while the spill program is referred to as an interim protection measure due to its impact on water quality. The intent of the Fourth Revised Interim Stipulation was to develop a bypass system as an alternative to spill. The initial development of the prototype bypass system at Rocky Reach was to meet interim stipulation objectives. In 2002, FERC (and Chelan County PUD) consulted on the operation of Rocky Reach Dam and the construction and operation of a juvenile bypass system. NMFS determined through a Section 7 consultation that the proposed action would not jeopardize the listed species. Thus, the Rocky Reach juvenile bypass system should be considered an integral component of Chelan County PUDs efforts to minimize take under either action alternative. However, the bypass is specifically linked to the HCP. Alternative 2 of the FEIS now evaluates a sluiceway bypass system that could

be recommended by NMFS to protect listed species in the event that the bypass system proves ineffective.

Miscellaneous Comments

Comment 63 *Disclose the potential for an increase in noxious weeds under drawdown.*

Response 63 This discussion was added to FEIS Section 4.4.2.1, Project Area.

Comment 64 *A risk assessment should be completed for the HCPs because they rely too heavily on the adaptive management strategy.*

Response 64 A risk assessment is a quantification of the potential adverse effects that an action can have on a population of organisms. The studies the applicants are completing in determining salmonid mortality through the projects replicate the outcome of a risk assessment. The adaptive management strategy is not related to risk assessments. Adaptive management is a process used to ensure that mitigation measures will be effective in reducing mortality, and if the measures are not effective, then another approach that is more effective would be adopted.

Comment 65 *Provide more information on the amount of energy needed from the three projects, and whether the need is a deficit for the area or a deficit in meeting exporting needs.*

Response 65 **FEIS** Section 1.6, Background has been revised to include the most recent Federal energy surplus/deficit projections and a description of the energy production and customers for the three dams.

Comment 66 *Identify in the FEIS USEPA's Clean Air Act Section 309 responsibility to review the document.*

Response 66 This information was added in FEIS Section 1.6.2.10, U.S. Environmental Protection Agency.

Comment 67 *Additional diagrams or photos of each dam should be included to illustrate project features identified in Table 2-3 and passage routes with associated survival rates.*

Response 67 This information is provided in Figures 2-1, 2-2, and 2-3 and Table 3-4 of the FEIS. However, route-specific survival estimates are to be used as a last resort under Alternative 3 to assess compliance with the no net impact standard. They are also expected to be used as a last resort of listed species under Alternative 2, given NMFS's opinion that PIT-tag data provide the best estimate of survival because such studies provide a better assessment of direct, delayed, and indirect mortality.

Comment 68 *The EIS should include a table describing research needs and a priority and implementation schedule.*

Response 68 Under Alternative 2, the existing Mid-Columbia, Wells, and Rock Island Coordinating Committees would likely be responsible for assessing and prioritizing data needs. Also under Alternative 2, NMFS can require measures to minimize the incidental take of listed species and reporting and monitoring requirements necessary to ensure that the anticipated level of incidental take is not being exceeded. Under Alternative 3, the HCP coordinating, tributary, and hatchery committees would be responsible for assessing and prioritizing data needs for Plan species. Under Alternative 3, the survival studies would serve as the assessment for determining whether

or not the projects were complying with the anticipated level of incidental take, as well as the extent and nature of additional research needs.

Assessing the survival rates of juvenile and adult fish passing the projects is the most important research need for both action alternatives. The primary focus of the alternatives is to protect the salmon and steelhead species as they pass the projects, and to mitigate for unavoidable mortality. The mitigation goals are determined by the effects of the projects on fish survival. Therefore, to set appropriate mitigation levels, accurate survival estimates are needed. Much of the other research needs are related to the quality of the mitigation that would be used to fine-tune the amount of mitigation required to achieve the mitigation goal. Under Alternative 2, the PUDs would be required to provide the required mitigation, but not necessarily the assessments related to the adequacy of the mitigation. Although this is also the case for some aspects of Alternative 3 (e.g., assessing if the tributary conservation funding provides a 2 percent mitigation level), other aspects are included in the provisions of the HCPs (e.g., survival studies for 3 years for all the Plan species). Although there are a large number of unknowns related to biological functions in the basin, many of these are independent of direct or indirect project effects.

Comment 69 *The EIS should state that dam releases have fewer temperature fluctuations with cool moments for fish refuge during hot periods.*

Response 69 Because of their large reservoirs, mainstem hydroelectric facilities within the Columbia River Basin often act as a thermal buffer—decreasing maximum and minimum variations in water temperature on both a daily and yearly basis. The exact benefit, if any, of this effect to Plan species has not been determined. While a slight reduction of maximum daily temperatures could benefit Plan species that migrate during the summer or early fall, the corresponding increase in minimum daily temperatures could be detrimental. However, the Mid-Columbia River projects are run-of-the-river facilities that have limited ability to manipulate water temperatures in the basin. The large upstream storage reservoirs, which are outside the project area, are thought to have much greater influence over water temperatures in the river.

Comment 70 *The DEIS states that the Washington Department of Ecology is not permitting new water rights to withdraw water from several of the Mid-Columbia River tributaries due to dewatering concerns. The FEIS should describe the effectiveness of this mitigation measure and the extent that dewatering still affects fish species of concern.*

Response 70 Because water rights in the basin are generally over-allocated, not permitting new withdrawals effectively means that there are no changes to existing dewatering conditions. As a result, this restriction is not functioning as a mitigation measure. Conditions of dewatering and effects on fish species are addressed in FEIS Section 3.2.10, Aquatic Habitat.

Comment 71 *Define "some degree of certainty" regarding the long-term operation of the projects, and which elements are subject to future negotiations.*

Response 71 Based on comments on the DEIS, the phrase "some degree of certainty" does not occur within the revised HCPs. Uncertainties relating to long-term operations at the project have also been minimized to the extent practical in the revised HCPs. In addition, with the continued studies and mitigation measures in place at the projects since 1998, the PUDs have obtained a better understanding of which measures are needed to meet the HCP performance standards. The PUDs will be able to more easily track and budget for implementation of these measures over both the short and long term. Effort will be expended in implementing and developing mitigation measures that meet no net impact standards rather than the time-consuming process of negotiating

and consulting with agencies and other entities to develop standards that are agreeable to all parties involved. In the event that the PUD(s) fail to meet pertinent survival standards for Plan species (Phase II designation) after Phase I is complete, the coordinating committees would determine what additional measures are necessary to meet those standards. At this time, NMFS does not know what these measures would be, but the measures could include additional structural modifications (for example, surface collectors or fish bypass systems) or other operational measures (for example, increased spill or altered turbine usage and spill patterns).

Comment 72 *Define "best efforts" in terms of HCP compliance by the PUDs.*

Response 72 The DEIS misrepresented the use of this term. The HCPs only refer to "best efforts" in relation to maintaining and operating the adult fishways according to the current Detailed Fishway Operation Plan, not the performance standards (93 percent juvenile dam passage and 91 percent total project survival standards). The term means that the PUDs will maintain and operate the adult fishways to the established criteria, or a subsequent higher standard. The misuse of the term "best efforts" has been corrected in the FEIS.

Comment 73 *Define and provide examples of "maximum extent practicable" when referring to mitigating the impacts of takings.*

Response 73 This terminology is taken directly from Section 10 of the Endangered Species Act (Section 10(a)(2)(b)(ii)). No specific definition is provided in the Act, although it is assumed to include such factors as physical, economical, and legal constraints.

Comment 74 *The EIS should also consider normative river and multi-species restoration, the risk of HCP assumptions being incorrect, the potential for the alternatives impacting other species or species life histories, and the feasibility of introducing coho salmon.*

Response 74 The normative river concept was advanced by both the National Research Council (1996) and the Independent Scientific Group (1996). Simply put, this concept articulates that on a broad scale, river management strategies and mainstem habitat improvements should emphasize reestablishing key functions or functional attributes of a normative river. The Tribal Plan, Spirit of the Salmon (CRITFC 1996) agreed with this approach, stating that, "To support anadromous fish, mainstem habitat must be returned to natural conditions closer to those that existed prior to construction of the dams." NMFS also recognizes the importance of this concept, which has been included in the Endangered Species Act Implementation Plan for the Federal Columbia River Power System biological opinion (NMFS 2000a). Consistent with this concept, the fundamental strategy of this plan is to implement recovery actions broadly and comprehensively across all aspects of the salmon life cycle in recovering listed species.

The FEIS considers two action alternatives having different structural and operational measures, different procedural pathways, and different risks in terms of the likelihood or timing of protective measures being implemented. In either case, NMFS would consider the normative river concept when participating in the Mid-Columbia, Rock Island, and Wells coordinating committees (Alternative 2) or in the HCPs' coordinating committees (Alternative 3). Compared to Alternative 2 (which would primarily focus on listed species), Alternative 3 would likely provide greater opportunities for considering the normative river concept because it applies to all Plan species and establishes a Plan Species Account. These funds could be used to improve habitat conditions within both mainstem and tributary habitats—positively affecting life-history stages in addition to those actions taken at the projects to increase migration survival rates.

Alternative 3 is consistent with the multi-species restoration approach because it includes both listed and unlisted species as Plan species. This provides equal protection requirements for these species (including coho salmon) through the establishment of consistent, measurable performance standards. Alternative 2 would most likely provide a higher level of protection for the listed Plan species than for the unlisted Plan species because NMFS could only obtain protective measures for these unlisted species through litigation or other processes, such as FERC relicensing. Therefore, the potential for implementing protection measures that select only for certain species or life stages is likely greater under Alternative 2 than Alternative 3.

Comment 75 *If the HCPs set an initial 5-year period of evaluations, with up to 3 years of evaluations, then annual payments to the Plan Species Account may not begin until 8 years from the commencement of Phase I. To correct this decrease in funding, the initial payment should be increased.*

Response 75 The initial payment to the Plan Species Account would occur within 90 days of the effective date of the HCPs, and subsequent annual payments would be due on January 31 for each subsequent year. The tributary committees can also request that the PUDs contribute, in advance, any of the annual contributions during the first 15 years (for Chelan County PUD's projects) or 10 years (for Douglas County PUD's Wells Project) of the agreement.

Comment 76 *Missing on page 2-49 (Section 2.6) of the DEIS is a discussion of how the action alternatives lead to an improvement and not an extinction of the affected species.*

Response 76 Section 2.6, Alternative Comparison of the FEIS is a comparison of the affected species under each of the alternatives, and is not meant to be a comparison of the results of implementing any of the alternatives. A discussion of the survival improvements for each of the alternatives is located in FEIS Section 4.2, Fisheries Resources.

Comment 77 *Under Alternative 2, the EIS should discuss the requirement of NMFS and the Tribes to consult under the Secretarial Order. The EIS should confirm that NMFS and the Department of the Interior maintain their authorities under the Federal Power Act.*

Response 77 See FEIS Section 1.1, Introduction regarding other Federal laws, regulations, and statutes and their relation to the HCPs, as well as FEIS Section 4.12.17, Legislation Pertinent to Tribal Governments regarding consultation requirements between NMFS and the Tribes.

Comment 78 *The spill for Wells Dam is not clear; is it a step pool or cascade structure?*

Response 78 Table 2-2 of the FEIS provides a description of each of the projects. The spill gates at Wells Dam are a leaf-gate configuration. Although the gates open from the bottom, the water still plunges into the tailrace, which will result in an increase of total dissolved gas. However, the Wells Dam spillway has been modified into a juvenile bypass system, which is more efficient than an unmodified spillway at passing fish. Substantially greater numbers of fish can be passed at the project with a minimum amount of spill. The reduction in the spill volume also results in minimizing dissolved gas levels downstream when river flows and generation constraints result in involuntary spill.

Comment 79 *The EIS should state whether sediment deposition behind the dams would require dredging.*

Response 79 Text was added to FEIS Section 3.2.10.1, Reservoir Habitat explaining that dredging is not part of the routine maintenance at the projects, and reservoir dredging is not necessary to maintain a navigation channel.

Comment 80 *The EIS should further discuss whether the Rocky Reach bypass system can achieve a 98 percent survival rate, and whether spill should be increased to obtain the HCP performance standards.*

Response 80 This comment appears to confuse the statement that the Rocky Reach bypass could achieve a 98 percent survival rate, with an overall survival rate for all fish passing the project. The statement is specific to the bypass system, and the bypass survival rate would be factored with the survival rates for other passage routes to determine the calculated dam passage survival rate. Information in the FEIS does not suggest from this data that the performance standards for the HCPs could be achieved with only use of a bypass system. The revised HCPs specifically note that the calculated dam passage survival standard is a measurement of last resort (see Figure 2-4 of the FEIS). The prioritized survival standards for juveniles are measured project passage and measured dam passage. Studies utilizing paired releases of juvenile Plan species would most likely be necessary to measure these standards. In these studies, the overall survival estimate, not the estimated survival rate through a specific route of passage, would be applied to the applicable standard by the coordinating committees when making HCP phase determinations for Plan species.

Comment 81 *The alternatives were not ranked in their ability to achieve protection and recovery of the Tribal trust property.*

Response 81 The hydroelectric projects do not occur on Tribal trust property, with the exception of the Wells hydroelectric project. Effects of the alternatives on the Tribal treaty resources (salmon) are described in FEIS Section 4.2, Fisheries Resources regarding impacts and benefits of the action alternatives. Because there are benefits and disadvantages to all of the alternatives (refer to FEIS Section 2.6, Alternative Comparison), a ranking system is inappropriate. It is the responsibility of the reader to assess the information provided in the FEIS to make an informed decision as to the overall benefits of the alternatives.

Comment 82 *DEIS statements regarding Tribal rights to fish should be corrected.*

Response 82 See FEIS Section 3.11.3.3, Columbia River System for these changes.

Comment 83 *The DEIS infers that there was consent by Tribal biologists on the no net impact concept.*

Response 83 FEIS Section 2.3.4.4, HCP Performance Standards now omits the reference to Tribal biologists with regard to the no net impact concept. Also, see FEIS Section 4.12.17, Legislation Pertinent to Tribal Governments.

Comment 84 *The EIS should state that the USFWS must identify critical habitat for Columbia River bull trout.*

Response 84 This information was added in FEIS Section 1.5, Regulatory Framework.

Comment 85 *Section 7 and Section 10 have substantive and procedural differences that may not be adequately addressed in the DEIS.*

Response 85 See FEIS Section 2.6.2, Procedural Differences

Comment 86 *The hatchery compensation plan for Okanogan River sockeye salmon allows for substitution of summer/fall chinook salmon for sockeye salmon. The Colville Tribe opposes this action.*

Response 86 These substitution practices are provisions in the Wells Settlement Agreement, and will be phased out after 2005 under Alternative 3. Actually, spring-run chinook salmon are being raised as the substituted species by Douglas County PUD at this time, not summer/fall chinook salmon. After 2005, no net impact for Okanogan River sockeye salmon will be accomplished through implementation of a set of options identified in the Sockeye Enhancement Decision Tree (see Section 14 of the Wells HCP, Figure 3).

Comment 87 *The EIS should discuss the adult survival estimates presented by NMFS and the Idaho Cooperative Fishery Unit.*

Response 87 NMFS considered all of the available adult passage and survival information pertaining to listed Columbia River Basin salmon and steelhead in the preparation of its 2000 Federal Columbia River Power System biological opinion, including many studies conducted by the Idaho Cooperative Fish and Wildlife Research Unit. NMFS's best estimates of adult survival in the Columbia River Basin are generally summarized in Table 9.7-2 on page 9-189 of this document and in the 2002 Rocky Reach biological opinion (NMFS 2002a). Under the reasonable and prudent alternative, per project survival of Upper Columbia River spring-run chinook salmon and steelhead is estimated at 98.1 percent and 97.3 percent, respectively. Because of the general applicability of these numbers and NMFS's determination that they are the best numbers available, they were applied in the recent Rocky Reach biological opinion (NMFS 2002a). If the information cited above was available prior to 2001, it was considered by NMFS in the 2000 and 2002 biological opinions referred to above. However, this information may not have been included if NMFS determined that it was not the best scientific information available at that time.

Comment 88 *The EIS should discuss injury and mortality rates due to predation, and the effectiveness of predator control programs.*

Response 88 There are no estimates of losses due to predation at the projects. However, survival evaluations indicate a 6.1 percent and 2.5 percent loss of steelhead smolts passing through the Rocky Reach and Rock Island reservoirs, respectively. Predation probably constitutes a majority of these losses. The predator control program in the Rocky Reach and Rock Island project areas has removed about 75,000 northern pikeminnow between 1994 and 1999 (BioAnalysts 2000b). Over 17,000 northern pikeminnow were removed from the Wells Project area in 1998 and 1999 (Jerald 1999). Although an accurate estimate of survival benefits derived from these removals is unknown, the populations for northern pikeminnow appear to have declined since the start of the program. Since then, the average number of northern pikeminnow passing through the Rocky Reach fishways (April through November) has dropped from 6,508 to 3,151 fish; the counts at Rock Island have dropped from 24,016 to 7,666 fish.

Ruggerone (1986) documented substantial bird predation in the Wanapum Dam tailrace. He estimated the number of juvenile salmonids consumed ranged from 50 to 562 fish per hour. The number of salmonids consumed over a 25-day period during the peak salmonid outmigration was estimated to be between 111,750 and 119,250 fish, or about 2 percent of the estimated spring outmigration. Since that time, avian predator control measures have been started or enhanced at all projects. Although these measures have reduced bird predation in the project areas, no assessments were conducted to assess the exact survival benefits.

Substantial avian predation has been documented in the Columbia River estuary (NMFS 2000d). About 16,000 terns nesting on Rice Island consumed about 10.2 million (range: 7.4 to 13.2 million) outmigrating smolts during 1998, or approximately 11 percent (range: 8 to 14 percent) of the estimated 95 million outmigrating smolts (Roby et. al 2000). Following efforts to relocate the terns to other islands where the rate of salmonid consumption is lower, total consumption by Caspian terns in the Columbia River estuary in 2000 was reduced to 7.3 million (range: 5.7 to 9.3 million) smolts. This represents about a 38 percent reduction compared to the 1999 consumption rate.

Comment 89 *The Entiat River spring-run chinook salmon average escapement estimates (redds) based on dam counts (turnoff estimates) are in error and should alternatively rely on spawning ground survey redd count expansions for escapement and population trends.*

Response 89 The inaccuracies of the dam counts relative to expanded redd counts are presented in the FEIS. However, the relevance of this fact depends on the overall use of the data. For example, historical dam counts have been obtained through more uniform and consistent protocols than redd counts in the tributaries. Therefore, when comparing historical escapement trends, it is likely more appropriate to use only the dam counts rather than mixing the estimates.

Comment 90 *Entiat River average monthly flows are incorrect.*

Response 90 The written description of monthly flows in the Entiat River was incorrect in the DEIS. See FEIS Section 3.3.1.2, Associated Tributaries.

Comment 91 *Examine opportunities for coho salmon introductions.*

Response 91 Alternative 3 is consistent with the multi-species restoration approach because it includes both listed and unlisted species as Plan species. This provides equal protection requirements for these species (including coho salmon) through the establishment of consistent performance standards. Alternative 2 would provide additional protection measures for the listed species through the Section 7 consultation process, while other species would be protected through other processes, such as FERC relicensing. The Mid-Columbia River coho salmon are extirpated from the area, and are therefore not subject to protection under the Endangered Species Act. Although the PUDs have included coho salmon as a Plan species with respect to HCP coverage, this coverage would not be specifically required until a naturally producing population is reestablished. Protection for coho salmon under Alternative 2 would be through relicensing or license reopener proceedings, although the extent or mitigation requirements under these processes is unknown.

Comment 92 *The EIS should discuss the effects of elevated temperatures in the Okanogan River on adult sockeye salmon migration*.

Response 92 Although the inundation of the lower reach of the Okanogan River by the Wells Project can result in increased water temperatures in the reservoir, the majority of the temperature increases are the result of conditions in the Okanogan Basin. The naturally shallow lakes in the system, the low river gradient, and low summer flows accentuate the effects of solar radiation on water temperatures in the system. Adult fish have been observed holding in the Wells reservoir until water temperatures in the Okanogan River decrease to acceptable levels, but there is no evidence that suggests that they are holding downstream of the reservoir as a result of overall water temperatures in the reservoir. Water temperatures in the Okanogan River not only affect adult migration rates, but also severely restrict the use of the mainstem as juvenile rearing habitat. Mitigation for the effects of the Wells Project on sockeye salmon is identified in the revised

Wells HCP, which would focus on improving stream flow conditions in the Upper Okanogan watershed rather than hatchery production criteria used in the past.

Comment 93 *Monitoring is needed to address kelt passage and fallback guidance efficiency.*

Response 93 We agree that there are limited data on adult fallback and kelt passage at the projects. Although impacts from adult fallback would be included in the total project passage survival performance standard, there are no specific protocols for incorporating impacts to steelhead kelts in the overall passage survival estimates. However, the HCPs specify that the PUDs will identify adult fallback rates by the end of Phase I, and that the coordinating committees will determine the appropriate protection measures for steelhead kelts. These concerns will also be incorporated into the development and implementation of juvenile and adult passage measures, as well as project operation decisions.

Comment 94 *The juvenile holdover rate of summer chinook salmon is not adequately considered.*

Response 94 We agree that this is an unresolved outstanding issue with regards to the HCP performance standards. Although the subyearling (0-age) chinook salmon might be residualizing in the system, there are no data that suggest that this is a direct result of the Douglas or Chelan County PUD projects. As a result, there is no indication that the juvenile fish protection windows are not adequately protecting these fish. It is also unclear whether the operation of the projects incrementally impacts these fish during their holdover period over natural holdover conditions.

Comment 95 *The EIS should consider the socioeconomic needs of Indian Tribes for fishing and the benefits the Tribes obtain from harvest.*

Response 95 The information requested was added to FEIS Sections 3.7, Socioeconomics and 4.7, Socioeconomics.

Comment 96 *The FERC identifies three separate spring-run chinook salmon populations in the Methow, while the DEIS identifies the spring-run chinook salmon as a composite stock. Which is correct?*

Response 96 This EIS process is to address compliance with the Endangered Species Act. NMFS has determined through genetic evaluations that one Evolutionarily Significant Unit of spring-run chinook salmon occurs in the Upper Columbia River region. However, data for the individual river stocks are usually presented independently in the literature. The Quantitative Analysis Report also analyzed the runs separately.

Comment 97 *The EIS should analyze fish flows for the Columbia River.*

Response 97 As run-of-the-river projects, the PUD dams have limited control over flows in the Columbia River. Modified flows in the Columbia River are primarily the result of operations at large storage facilities in the Upper Columbia River and secondarily from operations to enhance migration conditions for listed fish as specified in the 2000 Federal Columbia River Power System biological opinion.

Comment 98 *The EIS should include steelhead radio-telemetry studies.*

Response 98 See FEIS Section 3.2.5.1, Upstream Migration of Adults that include the radio-telemetry studies.

Comment 99 *A sentence on page 3-89 of the DEIS is confusing.*

Response 99 The sentence has been corrected in FEIS Section 3.1.1.2, Associated Tributaries. The second reference to Entiat River should have been Entiat Mountains.

Comment 100 *Describe in quantitative terms the specific impacts to fish from hydroelectric and irrigation projects; commercial and sport fishing; logging; livestock grazing; water use by farms, cities, and towns; and municipal and industrial pollution.*

Response 100 It is not possible to quantify fish mortality attributable to irrigation projects; commercial and sport fishing; logging; livestock grazing; water use by farms, cities, and towns; and municipal and industrial pollution. However, this specific information is not needed to make an informed decision on selection of the project alternatives. For this FEIS, information that is needed pertains to the mortality through the three hydroelectric projects, and this information is provided in FEIS Sections 3.2.5, Adult Survival at the Projects and 3.2.6, Juvenile Survival at the Projects. For additional information on the effects of fish mortality from other impacts, please refer to *An Ecosystem Approach to Salmonid Conservation* (Spence et al. 1996), and the Federal Caucus's Basinwide Salmon Recovery Strategy (Federal Caucus 2000).

Comment 101 *The discussion of lethal measures used in avian control programs should not be a red-flag issue because shooting is conducted to enhance the scaring efficiency of firearms and pyrotechnics. The avian predator control programs at Wells Dam, Wells Hatchery, and Rock Island and Rocky Reach dams should be included in the EIS.*

Response 101 See FEIS Section 2.2.4.3, Predation. A discussion on shooting and lethal methods was added to this paragraph. Refer to FEIS Sections 2.3.2, Alternative 1 (No-Action) and 2.3.4.8, HCP Conservation Plan and Compensation Measures. Information was added concerning avian predator control programs at Wells Dam, Wells Hatchery, and Rock Island and Rocky Reach dams. Also see FEIS Section 3.2.10.2, Project Area Rearing to include other piscivorous birds; additional references on bird predation were added. Note that very little research on avian predation on fish in the Mid-Columbia River has been conducted, and no studies have quantified the exact amount of predation by birds, other than gulls, at the Wells, Rocky Reach, and Rock Island dams. Chelan County PUD (in conjunction with the University of Washington, WDFW, and NMFS) is currently assessing the impacts of piscivorous birds on juvenile migrating salmonids.

Comment 102 *The EIS does not address fish as a critical cultural resource.*

Response 102 Refer to FEIS Section 4.11, Cultural Resources regarding the importance of fish as a cultural resource.

Appendix

D

Chelan and Douglas County PUD Comments and NMFS Responses

Included in this appendix are letters received from the project applicants, Douglas and Chelan County PUDs. Following each letter are responses to their comments.

Chelan County PUD Letter D-29

NMFS Responses to Chelan County PUD Comments D-68

NMFS Responses to Douglas County PUD (DCPUD) Comments

Comment 1 *Page S-15, S.5.3 Alternative 3 (Applicants' Proposed Action – Project HCPs), second Paragraph, last Sentence. We request further clarification regarding the following statement, "(EIS prepared by FERC including a separate Section 7 consultation with NMFS regarding the effects of the agreements on listed species)."*

This paragraph indicates that FERC needs to prepare a second EIS for implementation of the HCPs. The parties expended considerable effort prior to preparation of the Draft EIS to avoid this unnecessary duplication. There is no rationale for FERC to prepare a separate EIS to implement the HCP.

Response 1 The FEIS was edited to reflect the comment in Section 2.3.4, Alternative 3 (Proposed Action – Project HCPs) and the corresponding section in the summary chapter. Although NEPA compliance is required to issue an incidental take permit, it does not necessarily require an EIS. The NEPA process is intended to provide an understanding of the environmental consequences of the proposed action to help a Federal agency make decisions. Although a FERC license action is separate from the NMFS action of issuing the permit, as a cooperating agency, FERC intends to use this EIS to make decisions on subsequent license actions relevant to implementation of the HCPs. In addition, the State agencies intend to use the information generated by this process to satisfy State environmental requirements. See NMFS responses to DEIS public comments, Appendix C, Response #19.

Comment 2 *Page S-22, Paragraph 1, line 5 and line 11. Please change the following two statements, "If juvenile dam passage survival …" to "If juvenile project passage survival"*

Response 2 This language is no longer applicable due to changes in the revised HCPs.

Comment 3 *Page S-22, Paragraph. 1, line 5. "If juvenile dam passage survival after <u>three</u> years of evaluations remains…" The Wells Implementation Agreement specifically calls for three years of survival studies within the five-year period known as Phase I. Phase I began in 1998.*

Response 3 This was meant to indicate that 3 years of assessment were required, and not that 3 additional years of study were needed. However, this language is no longer applicable due to changes in the revised HCPs. See NMFS responses to DEIS public comments, Appendix C, Response #57.

Comment 4 *Page S-29, Table S-2 Alternative Comparisons (Alternative 1). In the section labeled, "Continued Studies to Assess Survival" please clarify that continued survival studies at Wells Dam toward the goal of determining passage survival conditions at Rock Island and Rock Reach dams is not the responsibility of the Wells Project owner.*

Response 4 Reference to Wells Dam was removed to avoid confusion. See NMFS responses to DEIS public comments, Appendix C, Responses #21 and #22.

Comment 5 *Page S-35, Second Column, second to last Bullet. "determine whether the species can be expected to survive with an <u>adequate potential</u> for recovery under the proposed action…" Please define "adequate potential" in terms of interim recovery goals and standards. Would a greater than 50 percent probability of recovery be sufficient? How does, "adequate potential for recovery" relate to the "not likely to jeopardize the continued existence" standard spelled out in Section 7(a)(2) of the Endangered Species Act?*

Response 5 Section 1.3.1.1 of the 2000 Federal Columbia River Power System biological opinion describes the general analytical approach that NMFS uses to apply the jeopardy standard in the implementing regulations (Section 402.02 – definition of "jeopardize the continued existence"). This general analytical approach states that, for an action to avoid jeopardy, the mortality of listed salmonids within the different Evolutionarily Significant Units attributable to the action must be low enough to meet the following condition:

> *When combined with mortality occurring in other life stages, there is a high likelihood of population survival and a moderate to high likelihood of population recovery.*

For anadromous fish in the Columbia River Basin, NMFS has chosen the probability that 8-year geometric mean abundance will be greater than or equal to recovery abundance level in 48 years as the most conservative recovery metric. NMFS approximates "moderate to high probability" in its modeling efforts as "50 percent or greater likelihood of meeting the recovery abundance level in the specified time period." See NMFS responses to DEIS public comments, Appendix C, Responses #41 and #52.

Comment 6 *Page S-38, Table S-3 Environmental Comparison of the Alternatives (Page 3 of 8). Under "Fisheries Resources: Other Plan Species – Adult Reservoir Spawning", Alternative 1, 2 and 3 are listed as being: "Same as discussed for threatened and endangered species above." However, under the T & E section (above) there is no discussion of Adult Reservoir Spawning.*

Response 6 The FEIS was revised to reflect that there would be no change from existing conditions for the three alternatives, but that reservoir spawning primarily refers to fall chinook.

Comment 7 *Page S-39, Table S-3 Environmental Comparison of the Alternatives (Page 4 of 8). Under "Tributary Habitat Improvements" for Alternative 1, 2, and 3. Given that this document is intended to evaluate three possible environmental alternatives related to future operation of PUD dams, we are confused by the following statement: "Habitat improvements would occur through the implementation of non-PUD funded projects through Federal, State and local agency funding." This statement misleads the reviewer to conclude that habitat improvements will take place regardless of the selected alternative. Simply stated, under Alternative 1 and 2 the PUDs would not fund off-site habitat improvements. Under Alternative 3 the PUDs would fund tributary enhancement toward a 2 percent increase in survival per project for Plan species covered by the HCP. Under all three alternatives the agencies may pursue habitat improvements.*

Response 7 The heading titled Tributary Habitat Improvements of Table S-3 has been revised in the FEIS to more clearly indicate that only under the HCP alternative (Alternative 3) are the PUDs expected to provide funding for tributary improvements. However, habitat improvement projects will continue to occur in the Mid-Columbia River area from a variety of sources (e.g., Salmon Recovery Funding Board). This is expected to occur under all three alternatives. The QAR analysis indicates that additional measures will be needed to recover listed species, even if the HCPs are implemented. Therefore, other activities are identified that would aid in the recovery process, as well as assessing the cumulative effects of Alternative 3. Deleting this information from the table would be more confusing because it would give the impression that the HCPs would be the only effort being implemented to recover the species. See NMFS responses to DEIS public comments, Appendix C, Responses #12 through #14 for discussion of off-site mitigation and the Tributary Habitat Plan.

Comment 8 *Page S-40, Table S-3 Environmental Comparison of the Alternatives (Page 5 of 8). Alternative 1, Water Quality, Tributary Water Quality. We suggest removing references to agency-funded*

habitat work. The inclusion of agency funding of habitat projects only confuses the three environmental options being evaluated. Under Alternative 1 and 2 the PUDs would not voluntarily fund improvements in water quality in the tributaries. Under Alternative 3, the PUDs would voluntarily provide direct funding toward the improvement of tributary water quality. This clear distinction needs to be drawn between the three Alternatives.

Response 8 Same as DCPUD Comment #7 (above).

Comment 9 *Page S-40 and S-43. Table S-3 Environmental Comparison of the Alternatives (Page 5, 6, 7 & 8). Actions common to all three alternatives and outside the control of the decision related to the EIS should not be presented in this table. Similarly, the actions referred to under DCPUD comment no. 8 should also be applied to statements contained under subsections: Vegetation (Project Area, Associated Tributaries), Wildlife (Threatened and Endangered Species), Land Use (Associated Tributaries), Economics (Tributary Habitat Improvement), Recreation (Tributary Habitat Improvements, Columbia River System) and Cultural Resources (Tributaries).*

Response 9 Same as DCPUD Comment #7 (above). The EIS must assess cumulative effects of the proposed project. This table summarizes information contained in the EIS, and even if there is no difference between the alternatives, we need to show that this topic was evaluated.

Comment 10 *Page 1-6 and 1-7. 1.5.2.1 Endangered Species Act Requirements for Non-Federal Actions. "The No Surprises Policy and Adaptive Management" These two policies appear to be in conflict when it comes to implementation under the proposed HCP. Please describe how conflicts between the two policies will be mediated during the implementation of Alternative 3.*

Response 10 The No Surprises Policy section states that the regulation means that, "as long as an HCP is being properly implemented, the Section 10 permit is valid and nothing more can be required." It further indicates that "mitigation will remain as agreed." Adaptive management is an integral part of the HCPs because some of the mitigation identifies response-based requirements or goals. These goals have been agreed to and will not change, but the measures needed to reach the goals are generally unspecified and will require an adaptive management approach to implement. Other mitigation levels are clearly identified in the HCPs, as well as specifications on how they could be adjusted in the future. The revised HCPs also identify contingency procedures for resolving disputes and define circumstances under which the parties could withdraw from the agreements and/or NMFS could revoke the Section 10 permits. NMFS's ability to withdraw in certain circumstances, such as a failure of the species to rebuild, is not limited by the No Surprises policy.

Comment 11 *Page 1-16. 1.6.3 Alternative 3 (Proposed Action), first Bullet on Page 1-16. Please modify the following statement: "evaluate project specific survival rates," to "evaluate project specific juvenile survival rates."*

Response 11 The text has been revised to be consistent with the revised HCPs and reads as follows: "Evaluate survival rates according to the HCP Survival Standard Decision Matrix."

Comment 12 *Page 1-32, 1.10 Background Summary, second Paragraph, second Sentence. "Therefore, this EIS is being developed for the purpose…whether or not to issue incidental take permits." This statement appears to conflict with the statement made on Page S – 15 and Page 2-32. The EIS purpose includes amendment of FERC licenses. For a further description of our concerns please see comment no. 1.*

Response 12 See response to DCPUD Comment #1.

Comment 13 *Page 2-14, Wells Dam, second column of text, last sentence of text in the first partial paragraph. We take issue with the following statement: "Therefore, the total direct and indirect mortality is likely similar to the 2 percent found at the Lower Snake River project bypass systems (NMFS 1998)." We disagree. The Wells bypass system is not similar to the Snake River screen bypass systems. The Wells system performance is superior to those found at the Lower Snake River projects. Survival assigned to this passage route should be similar to the estimated survival assigned to spillway passage routes.*

In contrast, the Snake River screen bypass systems utilize extensive turbine intake screens, small gatewell orifice passages, collection channel dewatering, dewatering in transport pipes, handling and delay in sampling facilities, and reintroduction back into the tailraces through low volume pipes located immediately adjacent to predator-plagued shorelines.

The Wells surface collection system does not utilize massive intake screens, orifice passageways, transportation pipes, handling facilities and low water tailrace discharges. The Wells surface collector guides fish away from the turbines and into the spillways where five high volume non-turbine passage routes are provided through the dam. Fish are introduced back into the tailrace turbine discharge where velocities are sufficiently high to prevent predator accumulation and where gull wires protect fish from avian predators.

We suggest using a combined estimate of direct and indirect mortality that ranges from 0 percent to 1 percent for the Wells surface bypass system.

Response 13 Because the Wells bypass system consists of a modified spillway design, NMFS believes that direct and indirect mortality rates through this route of passage are most likely to range between 1 and 2 percent (2 percent being the most conservative). The FEIS has been revised accordingly. See NMFS responses to DEIS public comments, Appendix C, Response #36 for additional discussion.

Comment 14 *Page 2-17, 2.2.3.2 Adult Passage, second full paragraph, first sentence. Please modify the following statement: "Survival rates of adult salmon and steelhead passing through the Mid-Columbia River has not been estimated due to insufficient radio-telemetry data." to "Survival rates of adult salmon and steelhead passing through the Mid-Columbia River have not been estimated due to an inability to differentiate tag loss, tag failure and fish loss." It is not presently possible to estimate adult survival in a statistically defensible manner with the present radio-telemetry technology.*

Response 14 The FEIS was modified to reflect the comment, as well as other comments in the DEIS.

Comment 15 *Page 2-23, Measures Planned, fourth Line. Please replace "negotiations" with "agreements."*

Response 15 The FEIS was modified as suggested.

Comment 16 *Page 2-23, Measures Planned. 1. Adult Passage.*

c. The Wells Settlement Agreement does not contain language that obligates the District to conduct modeling in the adult fishways.

e. The Wells Settlement Agreement does not include conditions to continuously operate the juvenile surface bypass system from April through August for adult fallback and adult downstream passage.

Response 16 At this time, NMFS agrees that because FERC never acted upon the Wells biological opinion (which expired in April of 2002), the Wells Settlement Agreement is the controlling document for the purpose of analyzing the no-action alternative (Alternative 1). The FEIS was modified accordingly. See NMFS responses to DEIS public comments, Appendix C, Response #50.

Comment 17 *Page 2-23, Measures Planned. 2. Juvenile Passage. a. The Wells Settlement Agreement does not contain requirements to operate the turbines at peak efficiency ratings.*

Response 17 We agree (see response to DCPUD Comment #16 above), and the FEIS was modified accordingly.

Comment 18 *Page 2-23 and 2-24, Measures Planned. 2. Juvenile Passage. b. Surface Bypass Operation – Please modify the following statement: "Operate at least one spillway bypass, 24-hours per day, throughout the juvenile downstream migration periods" to "Operate at least one spillway bypass, 24-hours per day, throughout 80 percent and 70 percent of the peak spring and peak summer juvenile downstream migration, respectively…"*

Response 18 We agree that the Wells Settlement Agreement requires Douglas County PUD to operate the bypass system 24 hours per day during 80 percent of the spring and 80 percent of the summer migration (see response to DCPUD Comment #16 above), and the FEIS was modified accordingly.

Comment 19 *Page 2-24, Measures Planned. 2. Juvenile Passage. c. Predators and d. Gas Abatement. Neither of these actions is outlined in the Wells Settlement Agreement. Please remove the statements from the EIS.*

Response 19 We agree (see response to DCPUD Comment #16 above), and the FEIS was modified accordingly.

Comment 20 *Page 2-25, 2.3.1.2 Rocky Reach Hydroelectric Project. Analogous sections are missing under Rocky Reach and Rock Island project descriptions that are present under the Wells Project description. Please add the following Section designations to the Rocky Reach and Rock Island project descriptions to allow a more rigorous comparison of actions proposed at different projects: Adult Fish Passage, Juvenile Fish Passage, Hatchery Based Compensation, and Monitoring and Evaluation.*

Response 20 These sections have been added to the FEIS as requested.

Comment 21 *Page 2-28, second full paragraph, fifth Line. The QAR analysis findings that, "even the removal of the Mid-Columbia River dams would not be sufficient to recover these species, if recent total life history survival rates continue," should be expressed in the Summary on Page S-16, S.5.3.2 HCP Baseline Conditions.*

Response 21 The summary section is developed by cutting and pasting information directly from Chapters 1 and 2 of the FEIS to maintain consistency. Detailed discussions concerning the QAR are in Chapter 5 of the FEIS and are not discussed in detail in Chapters 1 and 2.

Comment 22 *Page 2-29, 2.3.2.1 Wells Hydroelectric Project. 3. Hatchery Program – It is important to point out that under Alternative 1, 2 and 3, Douglas County PUD has the ability to reduce hatchery production (including summer and spring chinook, steelhead, and sockeye) based upon the results of survival studies. Also, under Alternative 2 and 3, NMFS has the authority to reduce or modify hatchery production of listed and non-listed species to remain consistent with their long-term recovery strategies for listed Upper Columbia River spring-run chinook and summer-run steelhead.*

Response 22 We agree that under Alternative 1, Douglas County PUD has the ability to reduce hatchery production based upon the results of juvenile survival studies. Hatchery production under Alternative 2 of the FEIS contemplates hatchery production levels similar to those defined in Alternative 1, except that hatchery production of all species may be modified or reduced to levels consistent with long-term recovery strategies for listed species. The same is true under Alternative 3, except that the revised HCP proposes to not change hatchery production levels until at least 2013. NMFS may require program modifications or reductions in 2013 and every 10 years thereafter.

Comment 23 *Page 2.35, 2.3.3.5 HCP Performance Standards, third full paragraph, last sentence. "In addition, the 91 percent survival standard also includes reservoir survival and the dam passage survival of returning adults." This statement is inaccurate as presented. The HCP was set up to measure 91 percent juvenile project passage survival. The 91 percent juvenile number was derived by assuming loss of adults (2 percent), assuming loss through the reservoir (2 percent) in addition to the 5 percent allowed loss at the dam. Further assumptions related to the 91 percent determination included an assumed 2 percent delayed mortality from hydro passage and a 2 percent credit for natural river fish loss.*

The agreement reached on the HCP does not include measurement of adult survival at a 95 percent CI +/- 5 percent. This is evident from the adult language in the implementation agreement, the timeline for completion of the Phase I studies (5 years) and based upon the knowledge that precise adult survival studies were not statistically or scientifically defensible at the time the Implementation Agreement was negotiated. The PUDs did not sign up to ensure adult survival from tailrace to tailrace at a rate of 98 percent irrespective of natural mortality.

It is important to point out that during the negotiations of the HCP, a 2 percent adult mortality figure was discussed. However, the final HCP Implementation Agreement was approved without referencing the measurement of the 2 percent adult mortality figure. The final agreement says "…and a net of 4 percent mortality from all other project effects (including but not limited to reservoir, juvenile delay, and adult mortality with credit for natural mortality)." Please remove all discussion that indicates the HCP has a 2 percent measurable adult mortality component.

Response 23 This language is no longer applicable due to changes in the revised HCPs. See NMFS responses to DEIS public comments, Appendix C, Responses #14 and #58.

Comment 24 *Page 2-41, Verification of Standards. We agree with the statements in the first and second paragraphs of this section related to the verification of standards.*

Response 24 Comment noted, although changes in the revised HCPs invalidate some of these statements.

Comment 25 *Page 2-56, Table 2-8 Environmental Comparison of the Alternatives (Pages 1 of 8). Please modify this table per similar concerns expressed in comment no. 7, 8 and 9. The DEIS is intended to compare actions related to the implementation of three environmental alternatives for*

fish mitigation at three FERC licensed projects (no-action, S. 7 and HCP). Descriptions of actions outside those proposed by the PUDs (agency-funded habitat enhancement actions) should be removed from the document.

Response 25 Agency-funded habitat enhancement projects are likely to occur in tributaries that will positively benefit Plan species under all three alternatives evaluated in the FEIS. The expected effects of these projects are discussed in the cumulative effects section (Chapter 5) of the FEIS and summarized in Table 2-8. Also, see responses to DCPUD Comments #7, #8, and #9.

Comment 26 *Page 2-56, Table 2-8 Environmental Comparison of the Alternatives (Pages 1 of 8), juvenile migration/survival standards. Please change, "project specific standards" under Alt. 1 to "Project specific fish passage standards."*

Response 26 Text was added to the FEIS to reflect the comment.

Comment 27 *Page 2-59, Table 2-8 Environmental Comparison of the Alternatives (Pages 4 of 8), Drawdown, Alt. 2. It should be mentioned that drawdown under Alternative 2 could only be considered during relicensing of the projects.*

Response 27 Text was added to the FEIS to reflect the comment. NMFS could also petition FERC to reopen the licenses and seek drawdown through a reopener proceeding. See NMFS responses to DEIS public comments, Appendix C, Response #24.

Comment 28 *Page 3-10, Figure 3-4 Geology of the Rock Island Dam Area. There are two identical categories for Grande Ronde Basalt. What is the difference between N2 and R2 Units? In the figure, there is no discernable difference between the two geological formations.*

Response 28 The figure was modified in the FEIS.

Comment 29 *Page 3-28, Steelhead, Line 2. Please modify the following statement: "Rock Island Dam averaged 2,600 to 3,700 fish" to "Rock Island Dam ranged from 2,600 to 3,700 fish." The same comment applies to Line 4 of this same paragraph.*

Response 29 Text was changed in the FEIS as requested.

Comment 30 *Page 3-28, Sockeye Salmon. Please standardize the years being compared to 10-year intervals. As presented, the intervals appear to be contrived to show a recent decline in numbers of sockeye passing Rock Island Dam.*

Response 30 Text was modified in the FEIS to reflect the comment.

Comment 31 *Page 3-29, Coho Salmon, Last sentence. This section should also note the release of millions of coho by Chelan County PUD at the Turtle Rock Hatchery. This facility continued to release coho through the mid-1980's.*

Note that coho ladder counts at Rock Island totaled only 475 fish between 1933 and 1943 (Mullan, 1983; Mullan et al., 1992). That is an average of less than 48 fish per year. The statement: "After completion of Priest Rapids Dam in 1960, peak escapement estimates probably never exceeded 10,000 fish" is misleading. The statement should be modified to indicate that few coho existed prior to the completion of Grand Coulee and Rock Island dams. The statement subtly implies a cause and effect relationship between the completion of Priest Rapids Dam and

the demise of the coho run. The Upper Columbia River coho salmon run had already been wiped out prior to construction of any mainstem Columbia River dams as is evident from fishway counts immediately following the completion of Rock Island Dam.

Response 31 Text was added to the FEIS to reflect the comment.

Comment 32 *Page 3-29, Table 3-1 Spawning Distribution of Anadromous Fish Species in the Mid-Columbia River Watersheds. Fulton (1968) appears to incompletely describe salmon and steelhead spawning in the Mid-Columbia Region. Please modify Table 3-1 to include the distribution of fish described below.*

Fall Chinook - Please add the Columbia and Methow Rivers to the watersheds utilized extensively by Fall Chinook.

Steelhead - Please add the Twisp and Chewuch Rivers and Libby Creek as being important Methow River tributaries for spawning steelhead. It should be noted that Salmon and Omak Creeks are not presently important steelhead habitats. "Simikameen" is spelled "Similkameen." Also note, steelhead do not have access to the Upper Similkameen River. Instead they only have access to the Lower Similkameen River. Enloe Falls blocks steelhead access to the Upper Similkameen River.

Sockeye – Extensive spawning ground surveys for sockeye have not resulted in documented sockeye spawning in the mainstem Okanogan River. Please remove the reference to the Mainstem Okanogan River as a tributary of the Okanogan River used by spawning sockeye. Please modify the sentence to state that the Osoyoos Lake sockeye population is almost entirely spawned in the Okanogan River, upstream of Osoyoos Lake.

Response 32 The title of the table in the FEIS was changed to indicate primary spawning areas. As such, we have no indication that the Methow River is a primary spawning area for fall chinook salmon. Radio-telemetry analyses (LGL 2001) indicate that less than 5 percent (2 of 44 fish) of the fall chinook salmon that passed Wells Dam were last detected in the Methow River. However, the mainstem Okanogan and the Similkameen Rivers were added for fall chinook salmon. The suggested changes were made for steelhead, although reference to the Salmon and Omak Rivers was deleted rather than modified. The sockeye salmon section was also modified, although the original text was meant to indicate that the primary spawning areas were upstream of Osoyoos Lake, in the Okanogan River and tributaries.

Comment 33 *Page 3-30, 3.2.3 Tributary and Mainstem Development, end of first Paragraph. The last statement in this paragraph is not entirely accurate. Hydroelectric facilities on the Cowlitz, Lewis and Willamette Rivers do not all contain adult fish passage facilities. Some transport fish by truck upstream of the projects and others are migrational blocks to migrating adult salmon and steelhead. Please modify the statement to read: "All mainstem Columbia and Snake river dams downstream of these projects are equipped with facilities to allow …"*

Response 33 Text was modified in the FEIS as suggested, to clarify the original intent of the statement.

Comment 34 *Page 3.2.4 Hatchery Programs, Page 3-31, First line on page 3-31. Please modify the percent of summer-run chinook salmon that are of hatchery origin in the Mid-Columbia River. 80 percent hatchery composition for this stock is not accurate. The following table indicates the best estimate of hatchery contribution for the watersheds covered by this EIS (Table 1). The hatchery contribution of fall chinook is also closer to 20-30 percent and not 50 percent.*

Table 1: Escapement to the Wenatchee, Methow and Okanogan Rivers of hatchery origin summer chinook (Table adapted from Murdoch and Petersen, 2000).

Return Year	*Wenatchee*	*Methow*	*Okanogan*
1991	*2.4*	*0.0*	*0.0*
1992	*1.5*	*0.0*	*3.5*
1993	*5.0*	*24.0*	*36.1*
1994	*12.0*	*45.0*	*48.7*
1995	*9.2*	*36.9*	*54.6*
1996	*4.9*	*15.8*	*59.3*
1997	*8.5*	*9.2*	*54.3*
1998	*10.7*	*22.2*	*29.9*

Murdoch, A. and K. Petersen. 2000. Survival of sockeye, spring chinook, and summer chinook salmon released from Rock Island Fish Hatchery Complex Facilities, 1989 through 1995 broods. Prepared for Public Utility District no. 1 of Chelan County. Washington Department of Fish and Wildlife, 600 Capitol Way N., Olympia, Washington 98501-1091.

Response 34 The original DEIS text was referring to the entire Columbia River Basin, not just the Mid-Columbia region. However, the requested information has been added to the FEIS to clarify the issue.

Comment 35 *Page 3-31, 3.2.4.2 Hatchery Compensation for Mid-Columbia Tributary Losses. There is no plan in place to compensate for Mid-Columbia Tributary Losses. Please replace, "Tributary Losses" with "Mainstem Passage Losses."*

Response 35 Text was changed in the FEIS as requested.

Comment 36 *Page 3-37, Rocky Reach, second Paragraph in section, last Line. There was no sockeye salmon passage study at Rocky Reach in 1993. The 1993 study was a chinook study. There was a sockeye passage study at Wells Dam in 1992. However, this study did not include any monitoring at Rocky Reach Dam. The 14 percent fallback estimate was derived from the 1997 sockeye monitoring effort only (English et al., 1998).*

Response 36 The between years comparison was intended to be for summer-run chinook salmon. Text was edited in the FEIS to clarify the findings.

Comment 37 *Page 3-38, Rock Island Dam, second Paragraph, first Line. There was no sockeye study at Rock Island Dam in 1993.*

Response 37 Text was changed in the FEIS to refer to the 1997 study.

Comment 38 *Page 3-42, 3.2.6.3 Juvenile Bypass Systems, <u>Wells Dam</u>, second Paragraph, last Sentence. We disagree with the assertion that the Wells bypass system likely has indirect mortality similar to the diversion screen bypass systems located at the Snake River projects. See DCPUD comment no. 13 for the rationale for not comparing the Wells Bypass system to the Snake River bypass systems.*

The Wells bypass system is a highly efficient <u>spill</u> bypass system. Indirect mortality resulting from passage through this system should be compared with indirect mortality estimates derived from spillway survival studies.

Response 38 See response to DCPUD Comment #13.

Comment 39 *Page 3-46, Rocky Reach, second Paragraph, last Sentence. The yearling fall-run chinook survival studies cited in this paragraph were conducted in 1998 not 1999. Also, the results from the Eppard et al. (1999) study were not accurately cited. Eppard et al. (1999) provides two estimates of Rocky Reach survival from yearling chinook release in 1998. Table 10, Page 38 of the report states Rocky Reach project survival, depending upon the model selected, as (0.867, $s\hat{E} = 0.065$) based upon the parallel SR Model and (0.859, $s\hat{E} = 0.042$) based upon the PR model.*

Response 39 Text was added to the FEIS to reflect the comment.

Comment 40 *Page 3-65, Icicle Creek. The 19 miles of historical habitat is disputed by USFWS personnel stationed in Leavenworth. Radio-telemetry studies conducted in 2000 by the USFWS indicated that a natural obstruction in the river restricted fish access into the upper watershed. The obstruction is located within the first 3 miles of river upstream of the existing barrier dam.*

Response 40 Text was added to the FEIS to reflect the comment.

Comment 41 *Page 3-72, Summer/Fall-Run Chinook Salmon, first Paragraph, eighth Line. We suggest the following modification to the defined spawning distribution of summer chinook in the Methow River. Summer chinook have been observed spawning downstream of French Creek near the mouth of the Methow River immediately upstream of the town of Pateros. This expands the spawning distribution from 38 to 42 miles of habitat.*

Response 41 Text was modified in the FEIS to reflect the comment.

Comment 42 *Page 3-72, Steelhead, ninth Line. Please modify the following statement, "Spawning occurs primarily in late March, but may extend into July." to "Spawning is initiated as early as late March and can extend into July." Based upon surveys conducted in 1999, peak steelhead spawning appears to be taking place in late April rather than late March.*

Response 42 Text was modified in the FEIS to reflect the comment.

Comment 43 *Page 3-74, Top of page, first partial Paragraph, last Sentence. The abandonment of planting catchable rainbow was intended to reduce incidental harvest on steelhead smolts although it likely also protects a lesser number of chinook salmon smolts. Please add steelhead smolts to the list of species whose incidental harvest has been reduced by the cessation of planting catchable rainbow trout.*

Response 43 Text was modified in the FEIS to reflect the comment.

Comment 44 *Page 3-74, Riparian and Stream Channel Condition, forth Paragraph, second sentence. Please modify the second sentence to state, "Ironically, the areas most susceptible to dewatering by low flow events are often the areas containing the highest…"*

Response 44 Text was modified in the FEIS to reflect the comment.

Comment 45 *Page 3-76, Fish Resources, line seven. Observations of bull trout in the Okanogan Watershed have been limited in recent history. We suggest removing bull trout as an "important" fish resource in the Okanogan Basin. This suggested change is consistent with surveys conducted by*

the USFS, Okanogan National Forest and conclusions reached in Washington State, Limiting Factors Analysis for the Okanogan River Watershed.

Response 45 Text was modified in the FEIS to reflect the comment.

Comment 46 *Page 3-77, Habitat Condition, first Paragraph, last Sentence. Please change, "The Wells Dam pool inundates the lower 17 miles of the Okanogan River." to "The Wells Project boundary includes the lower 17 miles of the Okanogan River."*

During normal operation, the Wells Project does not inundate the entire 17 miles of the Lower Okanogan River. The Wells Project boundary was drawn to encompass possible inundated lands during a worst-case scenario flood event. In effect Douglas County PUD has the right to inundate the lower 17 miles of the Okanogan River only during times when the Columbia and Okanogan Rivers experience a simultaneous 100-year flood event that for some reason might not be mitigated through storage at Grand Coulee and the Canadian Treaty Storage Projects.

Response 46 Text was modified in the FEIS to reflect the comment.

Comment 47 *3.3.1.1 Project Area, Page 3-83, Wells Dam, Rocky Reach and Rock Island Dam. Please standardize the months that average flows are compared between projects. We would recommend using June and September rather than using a mixture of months. Also note that average September flows referenced for Wells Dam (114,791 cfs) is much higher than the average September flows cited at Rock Island Dam (74,478 cfs). Given that Rock Island Dam is downstream of Wells Dam and that the Chelan, Entiat and Wenatchee Rivers all enter the Columbia River between Wells and Rock Island Dam, these averages appear to be incorrect. Average September flows at Wells Dam should be slightly less than the average September flows at Rock Island Dam.*

Response 47 Text was modified in the FEIS to reflect the comment.

Comment 48 *Page 3-84, Figure 3-5, Average Monthly Flows (cfs) in the Mid-Columbia River at Wells Dam. Average September flows at Wells Dam appear to be less than 80,000 cfs.*

Response 48 Text was modified in the FEIS to reflect the comment.

Comment 49 *Page 3-85 & Page 3-83, Figure 3-6, Average Monthly Flows (cfs) in the Mid-Columbia River at Rocky Reach Dam. According to the Figure, average June flows at Rocky Reach are in excess of 150,000 cfs not 136,147 cfs as cited on page 3-83.*

Response 49 Text was modified in the FEIS to reflect the comment.

Comment 50 *Page 3-87, Wenatchee River, first Paragraph, line 6. The Wenatchee River watershed drains 1,328 square miles not 1.328 square miles.*

Response 50 Text was modified in the FEIS to reflect the comment.

Comment 51 *Page 3-89, Entiat River, second Paragraph, line five. The maximum and minimum average monthly flows for the Entiat River are incorrect. Both numbers presented in the report do not match with USGS information and are highly unlikely given that the reported numbers exceed those of the Wenatchee and Methow Rivers.*

Please see Figure 3-9. The average monthly flows from this figure indicate that the Entiat River in June averages less than 1,800 cfs and in September averages less than 200 cfs. Please reconcile the text and Figure 3-9.

Response 51 Text and figures were modified in the FEIS to reflect the comment.

Comment 52 *Page 3-87, 3-89 & 3-91. Please standardize the average monthly flows being reported for the various tributary streams.*

Response 52 Text was modified in the FEIS to reflect the comment.

Comment 53 *Page 3-91, Okanogan River, second Paragraph, last Sentence. See DCPUD comment no. 46*

Response 53 Text deleted in the FEIS.

Comment 54 *Page 3-97, Wells Dam, first and second Paragraph. The temperature excursion cited at the Columbia River at the Wells Hatchery intake is in error. The water temperatures reported here were not collected at the hatchery intake but were collected from the hatchery spawning channel after water had been held in shallow ponds immediately downstream of the intake of the facility. Also, the readings were not collected from a systematic, calibrated subsurface monitor but were instead collected with a non-calibrated, hand-held thermometer, sporadically used to collect relative water temperatures by fish culture staff stationed at the Wells Fish Hatchery.*

Note that the mainstem Columbia River water quality data collected immediately downstream of Wells Dam (Chelan Falls) does not show water temperate excursions above the criteria established for state waters.

Response 54 The text in the FEIS was revised. See NMFS responses to DEIS public comments, Appendix C, Response #1 for a discussion of the influence of dams on water temperature.

Comment 55 *Page 4-1, 4.1.1.2 Associated Tributaries, first, second and third Paragraphs, (Alt. 1). This entire section should be deleted and re-written with emphasis on contrasting the three proposed environmental alternatives. Describing additional actions outside the three alternatives that may be funded regardless of the outcome of the HCP only confuses readers. This comment is similar to DCPUD comments no. 7, 8 and 9 (above).*

We suggest changing this section to describe the fact that under the No-Action alternative, no PUD tributary enhancement funds would be available. The agencies are free to spend money on habitat improvements common to all three alternatives so this entire section (4.1.1.2) provides no information related to the decision to select one of the three proposed alternatives.

This comment also applies to Page 4-3, 4.1.2.2 Associated Tributaries.

Response 55 See response to DCPUD Comments #7, #8 and #9 (above).

Comment 56 *Page 4-6, second full Paragraph, second Line. It is important to point out that drawdown is not an option under the no-action alternative (Alternative 1). It could be an option that is discussed through relicensing of the projects (Alternative 2) or by unanimous consent of the HCP signature parties under Alternative 3.*

Response 56 Drawdown is considered an option under Alternatives 2 and 3 because it could occur at relicensing. Text was modified in the FEIS to reflect this comment. See NMFS responses to DEIS public comments, Appendix C, Response #24.

Comment 57 *Page 4-17, Wells Dam, second bullet. Under Alternative 1, the District is not obligated in the Wells Settlement Agreement to operate the bypass system 24-hours per day during the period that encompasses 95 percent of the downstream migration.*

Response 57 Text was modified in the FEIS to reflect the comment (see response to DCPUD Comment #16 above).

Comment 58 *Off-Site Mitigation, Page 4-43, first Paragraph. Please add that the proposed Douglas HCP has a provision that if juvenile project survival is greater than 95 percent, the tributary funding package would be reduced from 2 percent to 1 percent. This comment also applies to the section titled: Tributary Habitat Improvements found on Page 4-43.*

Response 58 The comment no longer pertains to the revised HCP. The FEIS was modified to reflect the current HCP language. See NMFS responses to DEIS public comments, Appendix C, Response #14.

Comment 59 *Page 4-65. Please modify "4.9.2.1 Project Are" to "4.9.2.1 Project Area."*

Response 59 Text was corrected in the FEIS.

NMFS Responses to Chelan County PUD (CCPUD) Comments

Specific Comments

Comment 1 *Page S-15, 2-32, Alternative 3 (Applicants' Proposed Action – Project HCPs), 2nd paragraph. The text states that "the EIS required for implementing measures in the HCPs …" An EIS may not be needed in order to implement measures in the HCPs. In most cased an environmental checklist or an environmental assessment will be sufficient.*

Response 1 The FEIS text was changed to "NEPA compliance" instead of EIS. See NMFS responses to DEIS public comments, Appendix C, Response #19.

Comment 2 *Page S-15, 2-32, Alternative 3 (Applicants' Proposed Action – Project HCPs), 2nd paragraph. The text states that "implementing measures in the HCP would be undertaking by FERC with a separate Section 7 consultation with NMFS". It is the District's understanding that the HCPs will be presented to FERC with a request that they be incorporated into the project licenses. FERC's action many not require a new Section 7 consultation with NMFS and USFWS.*

Response 2 Consultation is required for all Federal actions. NMFS must consult with itself to ensure that its decision to issue an incidental take permit will not jeopardize the continued existence of the listed species. The amendment of existing licenses by FERC is a separate action from NMFS issuing a permit. Although the EIS is intended to satisfy NEPA compliance requirements for both actions, FERC must consult with NMFS and USFWS (the Services) concerning their action. Depending on the outcome of that consultation, FERC might need additional NEPA compliance documentation. See NMFS responses to DEIS public comments, Appendix C, Response #19.

Comment 3 *Page S-18, 2-35, last sentence before the start of Section S.5.3.6 and Section 2.3.3.6. The sentence reads "…to achieve 95 percent juvenile dam passage survival and 91 percent project survival." Replace the "and" between "juvenile dam passage" and "project survival rates" with an "or". While the word "and" is used in the HCPs, its use was an error. An errata sheet will be prepared for the final HCP on this issue. The intent of the parties was to require the measurement of 95 percent juvenile dam passage survival starting in 2003 as a default. However, the parties desired to leave the coordinating committee the discretion to forgo measurement of 95 percent juvenile dam passage survival and just measure the juvenile component of 91 percent project survival in 2003. There is not an obligation to measure 91 percent project survival in 2003. The coordinating committee will measure 91 percent project survival when a protocol can be developed.*

Response 3 Text was changed in the FEIS to reflect the comment. However, some of the language suggested in the comment is no longer relevant as a result of changes in the revised HCPs.

Comment 4 *Page S-23, 2.3.3.11, Project Cumulative Effects. This text attempts to summarize Section V "Reservoir As Habitat" of the HCPs. However, the summary omits an important concept. The District agrees to consider cumulative impacts as part of its land use decision making.*

Response 4 NMFS concurs that the PUDs agree to consider cumulative impacts as part of their land use decision making. This change has been included in Section 5.1 of the Wells HCP and Section 6.1 of the Rocky Reach and Rock Island HCPs, as well as in Section 2.3.4.11, Project Cumulative Effects of the FEIS.

Comment 5 *Page S-24, 2-41, "Term of the HCPs", first paragraph, first sentence. The text states that "the 50-year term of the HCPs would not begin until the incidental take permits are issued." While correct, this sentence is a bit misleading. The 50 year term of the HCPs starts when the "Agreement is executed by all Parties and regulatory approvals are received…" HCP, Section I "Term of Agreement". Issuance of the requested incidental take permit from NMFS is only one of the regulatory approvals that must be received in order for the HCPs to become effective.*

Response 5 This section was deleted from the FEIS. Also see NMFS responses to DEIS public comments, Appendix C, Response #49.

Comment 6 *Page S-24, 2-41, "Transition Period" mischaracterizes the current HCP activities. The PUDs are not conditionally implementing the HCPs. The PUDs have volunteered to perform activities that are consistent with the HCPs as a sign of good faith. The District is also implementing measures because even though the HCP is not in effect the 2003 deadline is approaching.*

Response 6 This section was deleted from the FEIS. See response to CCPUD Comment #7.

Comment 7 *Page S-24, 2-41, "Transition Period" mischaracterizes the interim protection plans. In 1997, with the full support of the NMFS and the USFWS, the PUDs voluntarily filed interim protection plans with the Federal Energy Regulatory Commission. The interim protection plans identified various portions of the HCPs that the District, NMFS and USFWS felt were worthwhile to implement in advance of completing the HCP negotiations. Measures were picked to assist the migration of newly listed Upper Columbia River steelhead. The interim protection plans proposed only a two year plan because the HCPs were expected to be in place within two years. The interim protection plans were informally expanded to include Upper Columbia spring-run chinook salmon upon their listing. The PUDs requested that FERC approve the measures contained in the interim protection plans. FERC initiated consultation with NMFS over this proposed action. The consultation has yet to be completed, and FERC has yet to take action on the plans. Due to the time taken to complete this consultation, the interim protection plans have expired.*

Response 7 Section 2.1 of the NMFS Biological Opinion on the Rocky Reach Juvenile Bypass System (dated March 11, 2002) provides a history of the interim protection plans. Although Chelan County PUD disagrees with a statement contained in the history indicating that Brian Brown's letter to Steve Hays (dated April 4, 2002) documented an agreement.

Comment 8 *Page S-26, 2-43, "Compensation for Unavoidable Project Mortality", first two sentences. The meaning of the first two sentences is not clear. The District has not modified any portion of the incidental take permit applications that were filed with NMFS.*

Response 8 This text is correct when referring to the negotiations leading up to the revised HCPs.

Comment 9 *Page S-26, 2-43, "Hatchery Compensation Plan Issue" and Page 1-12 Section 1.5.2.6 "Federal Trust Responsibilities to Indian Tribes" overstates the issue in dispute. The HCP requires that 7 percent of the "unavoidable project mortality" associated with each project be mitigated through hatchery supplementation. HCP Section III.1. The HCP goes on to define the initial hatchery production commitment (HCP Sections VIII.3. and 4). NMFS is in a position to evaluate the effects of the initial hatchery production commitment. However, hatchery production will vary over time depending upon the size of the runs. NMFS has been unwilling to opine that the hatchery program will always satisfy the Endangered Species Act. Since NMFS has been unwilling to define the hatchery levels that will satisfy the Endangered Species Act it is not*

possible to predict how the hatcheries will be utilized during the term of the HCPs. Hatchery production is a key incentive for the tribes' participation in and support of the HCPs as a comprehensive settlement. Without knowing how the hatcheries will be utilized during the term of the HCPs the tribes cannot effectively evaluate the benefits of the HCPs. As a result of this uncertainty the tribes are not supporting the HCPs.

Response 9 The FEIS text was modified to reflect the components of the revised HCPs and the agreed-upon solution to the dispute.

Comment 10 *Page S-29, 2-50, "Endangered Species Act Compliance." It is unknown whether the project's current licenses comply with the Endangered Species Act since they were issued prior to the adoption of the Endangered Species Act. Also, assuming the project licenses do not comply with the Endangered Species Act, under Alternative 1 the District could obtain incidental take permits addressing only listed species.*

Response 10 The statement is meant to indicate that there would be no future provisions under Alternative 1 to address the Endangered Species Act, and not that there is no compliance. Additionally, Alternative 1 has been changed to include the Rocky Reach biological opinion as existing conditions.

Comment 11 *Page S-30, 2-51, "Future Provisions for Other Aquatic Species". The table should acknowledge for all three alternatives that the District could submit incidental take permits under Section 10 of the Endangered Species Act as a means of addressing the Endangered Species Act.*

Response 11 NMFS concurs that, for non-Plan species listed (either currently or in the future) under the Endangered Species Act, the PUDs could, under any of the three alternatives, apply for incidental take permits under Section 10 of the Endangered Species Act as a means of addressing their effects on these listed species. This addition has been incorporated into the corresponding sections of the FEIS. See response to CCPUD Comment #10.

Comment 12 *Page S-31, 2-52, "Dispute Resolution." The table incorrectly includes "binding arbitration" as a means for resolving disputes. The text on Page S.17 paragraph 2 does a better job of explaining the HCP's dispute resolution process; but, does omit two of the exceptions to utilizing dispute resolution. See discussion above under "The Agreements" for more thorough overview of the HCP's dispute resolution process.*

Response 12 This comment is no longer relevant due to substantial changes in the dispute resolution process in the revised HCPs. See NMFS responses to DEIS public comments, Appendix C, Response #21.

Comment 13 *Page S-33, 2-53, Section S.7.2.3 "Alternative 3", first full paragraph, second sentence. The text reads that in part "there is no requirement to provide the benefit of the doubt to the species of concern with respect to gaps in the information base and NMFS has no authority to determine what constitutes the best available information to be utilized in support of any decisions." This sentence infers that the HCP dispute resolution process may not comply with law. Such an inference is not correct. In the HCP, NMFS has expressly reserved its authority to monitor, modify, suspend, revoke and re-instate, and enforce its incidental take permit outside the HCP dispute resolution process. HCP Section X.3-5, and Section XI.1.b. Furthermore, the dispute resolution process will not produce a result that is binding upon NMFS unless NMFS agrees. HCP Section XI.5.c. The dispute resolution process is mediation with a twist. The twist is that the mediator will issue a decision that can be entered into evidence in a later proceeding. HCP Section XI. 5.c. The reason for the decision is to facilitate settlement. No one knows what, if any,*

weight will be afforded the decision. Also, the parties' intent is that once the decision is rendered parties will not feel the need to proceed further. NMFS like any other agency has the authority to enter into dispute resolution processes. 5 USC Section 572(a), and 575(a)(1). Since a party may pursue any remedy available after exhausting dispute resolution it is in full compliance with the law. HCP Section XI. 3.c.

Response 13 This comment is no longer relevant due to substantial changes in the dispute resolution process in the revised HCPs.

Comment 14 *Page S-35, 1-31, Section S.8 "Decision to be Made", second to last paragraph, first sentence. The text states that "NMFS will prepare a biological opinion to determine if the implementation of the HCPs is likely to jeopardize the continued existence of listed species that are likely to occur in the Plan area. …" The text goes on to discuss issues NMFS will analyze in the biological opinion, and explains actions NMFS may take based upon the results of the biological opinion. The process NMFS describes in the DEIS for evaluating the incidental take permit applications filed by the District are not consistent with Section 10 of the Endangered Species Act. Section 10(a)(2) of the Endangered Species Act defines the process NMFS must follow to evaluate an incidental take permit application. 16 U.S.C. Section 1539(a)(2). This process does not require NMFS to consult with itself under Section 7 of the Endangered Species Act. Section 10 defines the complete process NMFS must follow to evaluate an incidental take permit application.*

Response 14 The Habitat Conservation Planning and Incidental Take Permit Processing Handbook 3.B.2.e (USFWS 1996) specifically states that, "In the case of issuance of a Section 10(a)(1)(B) permit, USFWS or NMFS must conduct an intra-Service (or internal) consultation to ensure compliance of permit issuance with the provisions of Section 7." It goes on to state in Section 3.B.4. that, "Although the provisions of Section 7 and Section 10 are similar, Section 7 and its regulations introduce several considerations into the HCP process that are not explicitly required by Section 10—specifically, indirect effects, effects on federally listed plants, and effects on critical habitat."

Comment 15 *Page S-35, 1-31, Section S.8 "Decision to be Made", second to last paragraph, first sentence. The text states that "if the NMFS' biological opinion finds that the proposed actions are not likely to jeopardize the continued existence of the listed species …, the permits can be approved." While true, NMFS must also make the findings required by Section 10 of the Endangered Species Act in order to issue the requested incidental take permits.*

Response 15 Text was deleted in the FEIS.

Comment 16 *Page S-41, 2-61, "Land Use, Project Area, Alternative 3". The text does not correctly reflect the HCPs. In the HCPs the PUDs will consider cumulative effects of land use decisions, provide the signatories to the HCPs with opportunity to provide comments on permitting decisions, and notify permit applicants that their proposed use or occupancy of may result in incidental take of listed species and require authorization of NMFS or USFWS. HCP Section V "Reservoir as Habitat".*

Response 16 Text was modified in the FEIS to reflect the comment.

Comment 17 *Page S-42, 2-63, "Economics, Project Area"; also, Page 4-61 Section 4.7 "Socioeconomic". Why is there no analysis of how spill and the other measures in each alternative reduce the generating capacity and energy generated from the projects? This is a very significant effect of all the alternatives given the energy emergencies facing the Western United States, the Northwest, and Chelan County. Reduced generating capacity and reduced energy output have a direct effect on the ability of the projects to meet peak load demands for the District's own loads,*

and to prevent or minimize energy emergencies in the Northwest and Western United States. The failure of the projects to meet peak load demands for the District's own loads exposes the District's loads to the extreme costs of energy in the Northwest and the West, and also to the risk that energy will not be available at any price. These issues vary dramatically between the three alternatives reviewed in the DEIS.

Response 17 Refer to the new Economics sections in Chapters 3 and 4 of the FEIS, Sections 3.8 and 4.8.

Comment 18 *Page 1-1, Key Terms, "No Surprises Policy". The District understands that the term "No Surprises policy" refers to the rules set forth in 50 CFR Section 222.303(g).*

Response 18 Text was modified in the FEIS to reflect the comment.

Comment 19 *Page 1-4, Section 1.5, "Regulatory Framework", third sentence. What does "other Federal laws and regulations" mean?*

Response 19 Although other Federal laws and regulations may require disclosure of the DEIS to the public, NEPA defines the public distribution and comment procedures. Therefore, the reference to "other Federal laws and regulations" was deleted from the FEIS.

Comment 20 *Page 1-9, continuation of Section 1.5.2.4, "FERC Regulatory Requirements", 3rd full paragraph, second sentence. Text reads "These measures will supercede any settlement agreements pertaining to Plan." Insert "Species" after "Plan."*

Response 20 Text was modified in the FEIS to reflect the comment.

Comment 21 *Page 1-10, Northwest Power Act, 1st paragraph, second sentence. The text reads "The Mid-Columbia utilities are subject to the Act ….". The term "Mid-Columbia utilities" is not defined in the DEIS. This DEIS relates to the projects operated by Chelan and Douglas County PUDs. Also, Chelan and Douglas County PUDs are not subject to the Northwest Power Act. FERC considers the plans developed pursuant to the Northwest Power Act when licensing the projects.*

Response 21 Text was modified in the FEIS to reflect the comment.

Comment 22 *Page 1-11, "Title 77 Revised Code of Washington", First sentence. The sentence addresses "wildlife". This reference is not correct for the purposes of the proposed agreements being reviewed in the DEIS. Relevant for these purposes is the State's responsibility to "preserve, protect, and perpetuate wildlife, fish, and wildlife and fish habitat." RCW 77.04.055(1).*

Response 22 Text was modified in the FEIS to reflect the comment.

Comment 23 *Page 1-13, Section 1.6.1 "Alternative 1 (no-action), 2nd paragraph, 2nd sentence. The text states "…the years to address engineering, bond, and resource related issues…". The inclusion of the term "bond" is not correct in this sentence. The project licenses have not been amended to address the issuing of bonds.*

Response 23 Text was deleted from the FEIS. Descriptions of alternatives are in Chapter 2.

Comment 24 *Page 1-16, 3rd paragraph, last sentence. Text reads "This allows the HCPs to be updated with information received during the comment period…". This sentence incorrectly explains the NEPA process. Comments received by NMFS on the DEIS will be considered by NMFS when*

preparing the FEIS. The HCPs are multiparty, negotiated settlement agreements. The fact that NMFS receives a comment on the DEIS does not mean that the HCPs will be modified.

Response 24 Text was deleted from the FEIS.

Comment 25 *Page 1-17, Section 1.7 "Background", 4th paragraph. The region faces economic hardship in 2001 as power shortfalls hit the region. The current January-through-July runoff forecast has the region's water supply at 55 percent of normal, assuming normal precipitation for the March-through-July period. If this year's water conditions match 1977's, the lowest on record, the council predicted 2001 shortfalls could approach 8000 MW-months, with the deficit in May reaching 3300 MW-months. If the conditions match 1944 conditions, a year with just slightly higher runoff than the current projection, the total energy deficit across the months of April through August is 5,600 MW-months, with the deficit in May reaching 2,700 MW-months. (The Northwest Power Planning Council, "Northwest Electricity Markets in 2001: Status and Proposed Actions", March 26, 2001). The report states "it is a virtual certainty that emergency operations will be necessary during spring and summer to keep the electricity system from suffering outages." (NWPPC, 2001)*

Response 25 Project economics are provided in new sections of the FEIS. Refer to Sections 3.8 and 4.8, Economics.

Comment 26 *Page 1-18, continuation of Section 1.7 "Background", 1st full paragraph, 1st sentence. Also, Page 6.5, definition of "Mid-Columbia River." On Page 1-18, the text defines the Mid-Columbia River as "the area of the river between the Chief Joseph Project and the confluence of the Yakima River." On Page 6.5, the text defines the Mid-Columbia River as "portion of the Columbia River that begins at its confluence with the Snake River up to the Chief Joseph dam." These two definitions are not consistent. The term "Mid-Columbia River" is not used in the HCPs. However, the HCP's Tributary Plan's, Plan Species Account can be spent only on projects "within the Columbia River watershed (from the Chief Joseph tailrace to the Rock Island tailrace), and the Okanogan, Methow, Entiat and Wenatchee River watersheds…". HCP Section VII.2.*

Response 26 Text was modified in the FEIS to reflect the comment and clarify "Mid-Columbia" and "Plan" areas.

Comment 27 *Page 1-14, Section 1.7.2.2 "National Marine Fisheries Service", 1st paragraph, 1st sentence. The text reads "Many of NMFS' past studies, listings, and rules are directly relevant to the Mid-Columbia hydroelectric projects. …". The term "directly" is not accurate. The documents discussed in this paragraph are "indirectly" relevant to Chelan and Douglas County PUD's hydroelectric projects. They are not "directly" relevant to Chelan and Douglas County PUD's hydroelectric projects because they do not relate to these projects. They relate to the Federal hydroelectric projects on the Columbia River.*

Response 27 Determinations of the direct relevance of data depends completely upon the question being raised, and not necessarily geographical proximity to the projects in question. For example, survival of fish through a large Kaplan turbine would likely be better estimated by studies at other projects with similar configurations (e.g., size of turbine, head, tailrace) no matter where they occur, than by looking at neighboring projects with similar sized Francis turbines or smaller, faster-revolving Kaplan turbines. The term "directly" has been replaced with "relevant" in the FEIS to clarify the intent.

Comment 28 *Page 1-29, Section 1.7.3.1 "Mid-Columbia PUD FERC Agreements", 3rd sentence. This sentence refers to the Rock Island Settlement Agreement. The tribes listed in the text are not the only signatories to this agreement. The parties to the Wells Settlement Agreement, while similar to those of the Rock Island Settlement Agreement, are not the same.*

Response 28 Text was modified in the FEIS to reflect the comment.

Comment 29 *Page 1-29, Section 1.7.3.2 "Major Bond and Sales Agreements for the Projects". This text is grossly incorrect. As of March 14, 2001, the District's total estimated bonds outstanding is $886,076,000.[1] This indebtedness is secured by the revenue generated by the District's consolidated hydro system.*

Response 29 Text was modified in the FEIS to reflect the comment.

Comment 30 *Page 1-33, continuation of Section 1.10 "Background Summary", 1st full paragraph, 2nd to last and last sentences. The text reads "Under the agreement, the utilities would have the ultimate authority in the decision making process, as long as the no net impact standards are being met. If all parties agree that the standards have not been achieved, the coordinating committees would have an increased role in the decision making process" These sentences do not correctly summarize the HCPs. For example: the District has the "ultimate decision on pursuit and implementation of Tools during Phase I" of the Juvenile Dam Passage Survival Plan. HCP Section IV.2.a.i. In Phase II of the Juvenile Dam Passage Survival Plan the coordinating committee has the decision making authority. HCP Section IV.a.6 – 8. In Phase III of the Juvenile Dam Passage Survival Plan the coordinating committee has the decision making authority related to continued measurement and evaluation. HCP Section VI.a.11. In the Adult Passage Plan, the agreement lays out the actions to be taken. HCP Section VI.b. With regard to the Hatchery Compensation Plan and the Tributary Compensation Plan the "JFP accepts the responsibility to develop plans and programs necessary to implement the Tributary Conservation Plan and the Hatchery Compensation Plan. HCP Section III.4.*

Response 30 The revised HCPs changed the roles of the PUDs and the coordinating committees. According to the revised HCPs, the coordinating committees would have the authority to determine the measures to be implemented under all phases of the HCPs. Although the hatchery and tributary committees would have primary responsibility for decisions relative to their respective areas, the coordinating committees would oversee the HCP implementation process.

Comment 31 *Page 2-2, Section 2.1 "Development of Alternatives". Throughout the development of the DEIS the District has and still expresses concern about the choice of alternatives in the DEIS. The DEIS has not chosen as alternatives measures or mixes of measures that seek to mitigate the effects of the projects on salmon and steelhead. NMFS chose as alternatives competing legal process for establishing the measures to mitigate the effects of the projects on salmon and steelhead. This is a very unusual, and questionable method for evaluating the environmental effects of the proposed HCPs. The DEIS should be amended to provide more traditional alternatives. Alternatively, the rational and legal authority for this decision is not clearly explained in the DEIS, and should be incorporated into the FEIS.*

Response 31 As a result of comments received on the DEIS, modifications were made to the HCPs, as well as the EIS alternatives. Alternative 2 now includes a broader range of activities that could be

[1] Official Statement, Public Utility District No. 1 of Chelan County, Washington $143,995,000 Chelan Hydro Consolidated System Revenue Bonds consisting of $65,620,000 Series 2001A and $78,375,000 Series 2001B, page iv (March 1, 2001).

implemented at the three projects, and is not a different legal process. The actions that could occur under each alternative have also been evaluated to determine costs per mitigation measure associated with each action alternative. Refer to Section 4.8, Economics of the FEIS.

Comment 32 *Page 2-2, Section 2.1 "Development of Alternatives", 5th paragraph, 4th sentence. Text reads "to be in compliance with the take prohibitions of Section 9, FERC would implement the measures …." FERC would be in compliance with Section 9 of the Endangered Species Act by implementing the provisions contained in NMFS biological opinion and incidental take statement. However, FERC is not obligated to do so. FERC may take other action as long as it is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species which is … critical…". 16 U.S.C. Section 1536(a)(2); Aluminum Company vs. BPA, 175 F.3d 1156, 4394-4395 (9th Cir. 5/10/99).*

Response 32 Chelan County PUD is correct that FERC or any other Federal agency formally consulting with NMFS or USFWS could disregard the provisions of a biological opinion and proceed with its proposed action, but it does so at its own peril because it will not be covered by the take provisions and may be subject to Section 9 enforcement actions (Bennett vs. Spear, 520 U.S. 154, 1997). A biological opinion provides the Federal agencies the Secretary of Interior or Commerce's expert "opinion, and a summary of the information on which the opinion was based, detailing how the agency action affects the species or its critical habitat. If jeopardy or adverse modification is found, the Secretary shall suggest those reasonable and prudent alternatives which [he] believes would not violate subsection (a)(2) and can be taken by the Federal agency or applicant in implementing the agency action." 16 USC § 1536(b)(3)(A). If a Federal action agency adopts and implements the Secretary's biological opinion and incidental take statement, the action agency would no longer be liable for take of listed species associated with the licensed activity.

Comment 33 *Page 2-7 Section 2.2.1.2 "Rocky Reach Dam", first paragraph, last three sentences. The text describing the rehabilitation work at Rocky Reach is outdated. The following edits are recommended so that the text is current:*

"…Units 1 through 7 are currently vertical shaft Kaplan turbines installed during the original construction in 1962, while fixed-blade propeller units were installed in Units 8 through 11 in 1971. Two of these fixed-blade propeller units have been rehabilitated and replaced with Kaplan turbines. A third unit is currently undergoing rehabilitation and the remaining unit is scheduled to be rehabilitated by June 2002. In addition, all but one of the original Kaplan units have been rehabilitated and replaced with more efficient Kaplan turbines. This turbine work is expected to increase juvenile fish passage survival."

Response 33 Text was modified in the FEIS to reflect the comment.

Comment 34 *Page 2-11, Table 2-4, and all text that incorporates or explains information conveyed in the table which includes but is not limited to the text in Section 3.2.6.4 and Table 3-3. The juvenile dam passage information included in the table does not take into account project specific information, and when project specific information is reviewed it is dismissed in favor of information developed from other hydroelectric projects without explanation. Set forth in Attachment A is the most project-specific survival information available for both the Rocky Reach and Rock Island projects. This information is primarily based on information collected at these projects through the various studies identified in the references. Copies of the studies are available upon request.*

Response 34 Table was updated in the FEIS with the most recent data.

Comment 35 *Page 2-12, 1st paragraph, last sentence. The text reads "the information also indicates that survival is higher through the spillway and bypass system than through the turbine units." What is the citation for this statement? The statement does not logically flow from the materials cited in the paragraph.*

Response 35 Text was deleted in the FEIS.

Comment 36 *Page 2-14, Rocky Reach Dam, 3rd sentence. The text reads "Passage efficiency tests … and 52 percent of the PIT-tagged steelhead…". "PIT-tagged" is not correct. These were "radio tagged" steelhead.*

Response 36 Text was modified in the FEIS to reflect the comment.

Comment 37 *Page 2-14, Rocky Reach Dam, 5th sentence. The text reads "In 1999, guidance … 32 percent of the chinook and 53 percent of the steelhead passed …". In both cases, these were radio tagged fish.*

Response 37 Text was modified in the FEIS to reflect the comment.

Comment 38 *Page 2-15, Rocky Reach Dam, 2nd paragraph, 1st sentence. Text reads "Studies at the dam have shown that between 8 and 18 percent …" This text is not consistent with the text on page 4-18 which uses 19 percent and not 18 percent. Nineteen percent is the correct number.*

Response 38 Text was modified in the FEIS to reflect the comment.

Comment 39 *Page 2-16, Rock Island Dam, 3rd paragraph, 3rd sentence. The text reads "the spill passage rates for other species were estimated at 20, 33, and 35 percent for sockeye, fall chinook and coho salmon in 1998." What is the citation for this information?*

Response 39 Text was deleted in the FEIS.

Comment 40 *Page 2-16, Rock Island Dam, 4th paragraph, 1st sentence. The text reads "A subsequent study indicated that survival rates through modified bay with deeper stilling basins may be near 100 percent …." What is the citation for this information?*

Response 40 Citation was added to the FEIS.

Comment 41 *Page 2-16, Section 2.2.3.2 "Adult Passage", 1st paragraph, 5th sentence. The text reads "The delay and stress that adults experience during passage through multiple dams may reduce their spawning success." Please explain the scientific bases for this information, and provide a citation for the studies relied upon to make this statement.*

Response 41 The referenced passage does not state that passage through multiple dams reduces spawning success, but that it ***may*** reduce spawning success. The available technologies cannot directly partition amongst individual hydroelectric projects the effect of passage through multiple dams on the spawning success of salmon and steelhead. However, based on other available information, it is reasonable for NMFS to hypothesize that (1) passage and/or delays through adult fishways can increase stress levels, (2) these stress levels may negatively affect adult fish, and (3) these stresses

are cumulative in nature and could ultimately affect the spawning success of adult salmon and steelhead.

That delayed migration can result in large numbers of pre-spawning mortalities for anadromous fish has been well documented (Godfrey et al. 1954; Gilhousen 1960). Similarly, a large body of scientific information indicates that juvenile fish are stressed while migrating past hydroelectric projects, and that these stresses are cumulative in nature and can result in reduced survival (NMFS 2000a,d). It is therefore reasonable to believe that adults may be similarly stressed while migrating through multiple hydroelectric facilities and that this could ultimately affect pre-spawning mortality rates or spawning success.

Comment 42 *Page 2-17, continuation of Section 2.2.3.2 "Adult Passage", 3rd paragraph, 1st sentence. The text reads "Survival rates of adult salmon and steelhead passing through the Mid-Columbia River have not been estimated due to insufficient radio-telemetry data." This is not correct. Currently, technology does not exist to measure adult survival. Therefore a technology limitation, not an insufficiency of radio-telemetry data, is the reason for no survival information.*

Response 42 Text was modified in the FEIS to reflect the comment.

Comment 43 *Page 2-17, Section 2.2.3.3 "Adult Reservoir Passage", 1st paragraph, 4th sentence. The text reads "However, the reservoirs can increase the potential for wandering or straying (lost orientation), that could lead to higher pre-spawning mortality or reduced spawning success (Volkman 1995)." This conclusion is not contained in Volkman 1995 and cannot be inferred from the radio telemetry data contained in Volkman 1995. No evidence exists to support these statements.*

Response 43 Text was deleted in the FEIS.

Comment 44 *Page 2-27, Section 2.2.3.3 "Adult Reservoir Passage", 1st paragraph, 5th sentence. The text reads "Higher water temperatures as a result of project reservoirs may also lead to higher prespawning mortality." What is the citation for this information?*

Response 44 The Environmental Protection Agency summarized a large body of scientific information on the effects of temperature in its 1999 report titled *A review and synthesis of effects of alterations to the water temperature regime on freshwater life stages of salmonids, with special reference to chinook salmon*. This report clearly indicates that prolonged exposure of adults to temperatures in excess of 18 degrees Centigrade is likely to result in some level of pre-spawning mortality or other negative effects such as loss of equilibrium, higher levels of pre-hatch mortality, and higher rates of developmental abnormalities. Temperatures in the Mid-Columbia River often exceed 18 degrees Centigrade during the late summer months when adult summer/fall chinook salmon, sockeye salmon, and steelhead are migrating. A determination with regard to how much the Mid-Columbia hydroelectric projects, Federal projects, and other factors have contributed to this situation is the subject of a total maximum daily load (TMDL), which is expected to be completed in 2002 or early 2003.

Comment 45 *Page 2-27, continuation of Section 2.3.2 "Alternative 2 (Section 7 Consultation)", 6th paragraph, 2nd sentence. The text reads "Evaluations conducted as part of the Quantitative Analytical Report (QAR) (NMFS 2000b) …" The QAR is also discussed in detail in Section 4.2.1 "Quantitative Analytical Report". The QAR has not yet produced a final, peer reviewed document. Furthermore, the document cited at NMFS 2000b is a draft internal NMFS document. NMFS has yet to produce a copy of this document after numerous requests. The District objects to NMFS citing QAR results anywhere in this document or in any other document (yet alone devoting 10*

pages to it in Section 4.2.1, pages 4-6 through 4-16) until the QAR results are made public, finalized and peer reviewed. This comment relates to all references to the QAR in the DEIS. Without a copy of the QAR the District has no way to comment on portions of the DEIS related to the QAR. The District reserves the right to submit comments on the QAR until it receives a copy of the QAR and has had sufficient opportunity to review the QAR. Nevertheless, based upon the information provided in the DEIS and the District's limited knowledge of the QAR, the District objects strongly to NMFS's use of the QAR results. Most of the conclusions relied upon the DEIS are drawn from the portion of the database that dates back to only 1980 (p. 4-7) while the entire database dates back to the 1960s. This misrepresents the long term database. Conclusions based upon long term database shows dramatically different outcomes when compared to the conclusions based upon the short term database. While NMFS acknowledges the existence of data going back to the 1960s, it is dismissed as potentially too "optimistic" without a thorough explanation. (p. 5-11) The best scientific information available is the entire database which takes into consideration ocean cycles that were known to be more productive than the ocean conditions in the 1980's and 1990's. During the 50 year term of the proposed HCPs ocean conditions are likely to cycle back to more productive periods similar to the 1960s. This rational is supported by the current 2000 and 2001 improvement in runs that is attributed to greatly improved ocean conditions.

Response 45 Comment noted. See NMFS responses to DEIS public comments, Appendix C, no. 25.

Comment 46 *Page 2-35, continuation of Section 2.3.3.5 "HCP Performance Standards" 1st full paragraph. This paragraph was re-written from its mirror paragraph on page S-18. The text on page S-18 provides a clearer explanation.*

Response 46 Text was modified in the FEIS to reflect the comment.

Comment 47 *Page 2-35, continuation of Section 2.3.3.5 "HCP Performance Standards" 2nd full paragraph, 2nd sentence. The text cites to the 1995 Federal Columbia River Power System biological opinion for the Lower Snake and Columbia River projects (NMFS 1995). NMFS 1995 biological opinion has been superceded by its 2000 biological opinion. In 2000, USFWS also issued a biological opinion for bull trout. Therefore, this text should be updated to refer to the current biological opinions.*

Response 47 NMFS's 1995 Federal Columbia River Power System biological opinion has been superceded by the 2000 Federal Columbia River Power System biological opinion. Concurrently, USFWS issued a biological opinion on the Federal Columbia River Power System for Kootenai River white sturgeon and bull trout. The FEIS text was updated accordingly.

Comment 48 *Page 2-35, continuation of Section 2.3.3.5 "HCP Performance Standards" 6th full paragraph, last sentence. The text reads "…to achieve 95 percent juvenile dam passage survival and 91 percent project survival." As explained in earlier comments, the coordinating committee will measure only 95 percent Juvenile Dam Passage survival. However, the coordinating committee may elect to measure the juvenile component of 91 percent project survival. If the results of the standard that was measured was not achieved, then the coordinating committee would identify the tool for the District to implement by the next migration. It may be necessary to revise the HCP text to clarify this process.*

Response 48 Text was modified in the FEIS to reflect the comment and based on changes in the revised HCPs.

Comment 49 *Page 2-49 Section 2.6.1 "Alternative 1 (No-Action)". The text under this heading is introductory to all the alternatives, not specific to Alternative 1.*

Response 49 Text was moved in the FEIS to be located ahead of the Alternative 1 description.

Comment 50 *Page 3-27, Section 3.2.2.2 "Abundance". This section should be updated with 2000 fish counts and with projected fish counts for 2001. Fish counts showed a dramatic increase in 2000 and are projected to be even better in 2001. This information is very significant. Without this information the text is misleading.*

Response 50 Additional information has been included in the FEIS.

Comment 51 *Page 3-37, Rocky Reach, 3rd paragraph 2nd sentence. The text reads "the cumulative delay at nine dams on the Columbia River likely decreases spawning success." What is the citation for this information?*

Response 51 See response to CCPUD Comment #41. The FEIS text was modified to read as follows: "Although any delay related to passage at one dam may not be significant, cumulative delays (should they exist) at nine dams on the Columbia River may decrease spawning success."

Comment 52 *Page 3-39, Rocky Reach, 3rd paragraph, 1st sentence. The text reads "Based on juvenile radio-telemetry evaluations conducted in 1998, approximately 49 percent of the radio-tagged steelhead and 61 percent of the radio-tagged spring-run chinook salmon passed the project via the powerhouse (English et al. 1999)." This data is not correct. The correct citation should be English et al. 1998, not English et al. 1999. Also, 49 percent should be 34 percent, and 61 percent should be 51 percent.*

Response 52 Text was modified in the FEIS to reflect the comment.

Comment 53 *Page 3-39, Rocky Reach, footnote 2. Footnote 2 reads "Radio-tagged fall chinook obtained from the East Bank Hatchery … in 1997 and 1998 (e.g., approximately 81 percent powerhouse passage in … via the powerhouse at significantly higher rates than the …" The reference to 1997 is not correct and should be deleted. English et al. 1998 related to 1998 and 1997. Also, the use of the term "significantly" is not correct in this sentence. The term "significantly" has a meaning in statistics. The term infers that statistics were used to test a hypothesis. The statement made in the sentence is not the result of a statistical test. Therefore, use of the term "significantly" infers a level of credibility to the sentence that is not correct.*

Response 53 Text was modified in the FEIS to reflect the comment.

Comment 54 *Page 3-40 continuation of Rocky Reach Dam, 1st paragraph, 1st sentence. The text reads "Lady et al. (2000) … and English et al. (1999) estimated that 58 and 40 percent of the radio-tagged…" The estimates of 58 and 40 are not correct. They should be 50 and 30.*

Response 54 Figure 22 in English et al. (1999) indicated that the 58 and 40 percent values provided in the DEIS are correct.

Comment 55 *Page 3-40, continuation of Rocky Reach Dam, 2nd paragraph, last sentence. The text reads "Although neither evaluation was able to … the pilot level survival evaluation conducted using radio-tagged steelhead in 1999 estimated direct and indirect survival at 89.7 percent (Lady et al. 2000), suggesting that the indirect effects associated with turbine passage are more significant than those seen at the bypass system or spillway." The radio tag study cited in this sentence indicates a lower than desired direct and indirect survival at the project. NMFS should clearly explain why it is appropriate to use the results of a radio-tag study in this instance when the study*

shows low levels of survival, and not use the results of radio tag studies in other instances when the results of radio tag studies show high levels of survival. The District continues to object to NMFS's inconsistent use of study results, and failure to acknowledge the results of studies that show survival levels favorable to the District.

Response 55 The survival data are used to the extent that their proven reliability will allow. The primary uncertainties related to radio-telemetry survival evaluations are associated with tag detectability, battery life of the tags, and tag failure rates. As a result, these uncertainties might not provide the accuracy level necessary to estimate overall survival, but do allow relative comparisons to be made between groups of fish for which the potential inaccuracies are less important. In this instance, the discussion concerned the relative differences in survival between fish passing the project through the powerhouse units, compared to those passing through the spillway or the juvenile bypass system. Because tag detectability, battery life, and tag failure rates are not expected to vary substantially at particular downstream detection points, based on the passage route of the fish, such comparisons are appropriate. Also see response to CCPUD Comment #34.

Comment 56 *Page 3-43 Rocky Reach, 1st paragraph 2nd sentence. The text reads: "Passage efficiency tests conducted … yearling chinook salmon and 51 percent of the PIT-tagged steelhead passed the project via this route (English et al. 1998a)." This sentence is not correct. 51 percent should be 52 percent, and PIT-tagged should be radio tagged.*

Response 56 Text was modified in the FEIS to reflect the comment.

Comment 57 *Page 3-43 Rocky Reach, 1st paragraph 4th sentence. The text reads: "Passage efficiencies in 1999 … 32 percent for chinook salmon, and 11 percent for sockeye salmon (Mosey et al. 2000)." This sentence is not correct. 11 percent should be 16 percent.*

Response 57 Text was modified in the FEIS to reflect the comment and included additional data.

Comment 58 *Page 3-43 Rocky Reach, 1st paragraph 5th sentence. The text reads "Radio telemetry evaluations in 1999 also indicated that about 57 percent of steelhead passed the project through the bypass." What is the citation for this information? The District is not aware of any study that produced this information.*

Response 58 Text was deleted in the FEIS.

Comment 59 *Page 3-43 Rocky Reach, 1st paragraph, last sentence. The text reads "The combined spillway and bypass … and between 62 and 64 percent for steelhead (Lady et al. 2000)." This information is not correct. 62 should be 72, and 64 should be 74.*

Response 59 Text was modified in the FEIS to reflect the comment and included additional data.

Comment 60 *Page 3-43 Rocky Reach, 2nd paragraph, 1st sentence. The text reads "In both 1997 and 1998…". This is not correct. The evaluation was done only in 1998. The evaluation was not done in 1997.*

Response 60 Text was modified in the FEIS to reflect the comment.

Comment 61 *Page 3-43 Rocky Reach, 2nd paragraph, 2snd sentence. The text reads "In 1998, the bypass efficiency for naïve chinook salmon was substantially lower (19 percent) … (English et al. 1998a)." This is not correct. 19 percent should be 22 percent.*

Response 61 Page 28 in English et al. 1998a indicates the overall guidance efficiency for East Bank Hatchery chinook salmon at 19 percent.

Comment 62 *Page 3-43, Rocky Reach, 5th paragraph, 3rd sentence. The text reads "The temporary bypass outfall site, located in front of the turbine unit four upwelling, …" This is not correct. Unit four upwelling should be replaced with unit three upwelling.*

Response 62 Text was modified in the FEIS to reflect the comment.

Comment 63 *Page 3-44, Section 3.2.6.4 "Total Project Survival – Juvenile Migrants". The discussion of project survival is not correct. The obligation is that "The District shall also achieve and maintain 91 percent project survival … which means that 91 percent of each Plan Species, juvenile and adult combined, survive project effects, including delayed mortality wherever it may occur." HCP Section IV.1.a. The first sentence in this section of the DEIS fails to account for the fact that project survival includes "delayed mortality wherever it may occur." Also, the HCP does not define a protocol for measuring project survival as inferred from the DEIS. The HCP leaves it to the Coordinating Committee to establish the measurement protocols. HCP Section IV.3.c.*

Response 63 See NMFS responses to DEIS public comments, Appendix C, Responses #29, #36, and #57.

Comment 64 *Page 3-47 Section 3.2.7 "Overall Fish Passage Survival". 1st paragraph, 3rd sentence. The text reads "Based on the small amount of information that is available, the average survival of adult spring-run chinook salmon and steelhead is estimated at between 77.8 percent and 88.9 percent for the entire Mid-Columbia River reach…". What is the cite for this information? The District is not aware of any methodology to measure adult survival.*

Response 64 The DEIS reports survival estimates derived from adult radio-telemetry studies in the Columbia River upstream of Priest Rapids Dam conducted by Steuhrenburg et al. (1995) in 1993. This information was used to provide survival estimates of 77.8 to 88.9 percent (equating to an average per project survival rate of 95.1 to 97.7 percent) for adult Upper Columbia River spring-run chinook salmon across the five FERC-licensed Mid-Columbia River projects. However, these results are likely biased low because of problems associated with the tags, receivers, and software used at the time (Wainwrite et al. 2001).

Analysis conducted as part of the 2000 Federal Columbia River Power System biological opinion estimated total (natural and project-related) per project survival rates (current and under the reasonable and prudent alternatives outlined in the biological opinion) ranging between 97.6 and 98.1 percent for adult Upper Columbia River spring-run chinook salmon and 96.8 to 97.3 percent for adult Upper Columbia River steelhead. NMFS believes these are the best available estimates and are generally applicable to the FERC-licensed projects on the Columbia River.

NMFS again reviewed the available adult survival and radio-telemetry information pertaining to Upper Columbia River spring-run chinook salmon and steelhead in the 2002 Rocky Reach biological opinion. NMFS concluded that, "due to the limited amount of radio-telemetry information available for the Mid-Columbia River system, the pitfalls associated with utilizing radio-telemetry data to assess site-specific survival, and the environmental and species differences of the natural and impounded river systems evaluated, it is not possible to differentiate between natural and hydrosystem caused mortality at this time" (2002 Rocky Reach biological opinion – Section 6.2.3). Thus, taking into account natural mortality, which

undoubtedly occurs, it is likely that the adult mortality resulting from project-related effects in the Mid-Columbia River is currently less than 2 percent for listed species.

The FEIS text was modified accordingly.

Comment 65 *Page 3-96, continuation of Section 3.3.2 "Water Quality", 1st full paragraph, 1st sentence. The text reads "Although extensive evaluations have been conducted under controlled or laboratory conditions, the effects of specific total dissolved gas levels on fish in a river environment is relatively unknown." This statement is not correct. The effects of total dissolved gas on fish has been extensively studied in the Mid-Columbia as part of the 2000 Federal Columbia River Power System biological opinion.*

Response 65 NMFS did summarize the total dissolved gas-related physical and biological monitoring studies conducted since 1995 in Appendix E of the 2000 Federal Columbia River Power System biological opinion. The FEIS text was modified accordingly.

Comment 66 *Page 3-109, Section 3.4.4 "Rare Plants". The text states that Ute ladies' tresses (Spiranthes diluvialis) do not occur in or near the immediate project area of the dams. This is not correct. Recently, a Ute ladies'-tresses was determined to be present in the Rocky Reach reservoir shoreline area. This hydrophilic orchid would be affected by drawdown or other actions that would remove its water source. P. Fielder, pers. comm.*

Response 66 Text was modified in the FEIS to reflect this new data.

Comment 67 *Page 4-18, continuation of Section 4.2.2.1 "Rocky Reach Dam", 2nd paragraph, 2nd sentence. The text reads "Survival estimates for steelhead ranged from 87.0 percent to 111.9 percent …" This is not correct. 111.9 percent should be 101.0 percent.*

Response 67 Text was modified in the FEIS to reflect the comment.

Comment 68 *Page 4-18, continuation of Section 4.2.2.1 "Rocky Reach Dam", 3rd paragraph, 2nd sentence. The text reads "Under Alternative 1 however, there is no requirement to implement these additional measures." This is not correct. Under alternative 1 fish protection and enhancement measures can be implemented through the pending Mid-Columbia proceeding at FERC, and during relicensing.*

Response 68 NMFS concurs that, under Alternative 1, some protection and enhancement measures could be implemented through the pending Mid-Columbia Proceeding at FERC and during relicensing. The FEIS text was modified accordingly.

Comment 69 *Page 4-18, continuation of Section 4.2.2.1 "Rock Island Dam", 2nd paragraph, 2nd sentence. The text reads "Between 1995 and 1998, over 26,000 predatory …" This should be updated by replacing 1998 with 2000, and 26,000 with 34,000. West, T. 2001. Northern Pikeminnow (Ptychocheilus oregonensis) Population Reduction Program Rocky Reach and Rock Island Dams.*

Response 69 Text was modified in the FEIS to reflect the comment and more recent data.

Comment 70 *Page 4-20 continuation of "Adult Migration/Survival", 2nd full paragraph, 2nd sentence. The text reads "It is reasonable to assume that some portion of the adult bull trout populations pass through the turbines and spillways, either voluntarily or involuntarily, given their presence in the project area and use of project fishways." What is the citation for this information? Why is it*

reasonable to assume a correlation between presence of bull trout in the fishway and bull trout passing through turbines and spillways? The District is aware of no evidence supporting this statement.

Response 70 The draft report *Movements of Bull Trout Within the Mid-Columbia River and Tributaries 2001-2001* by Stevenson and Hillman (2002) supports the assumptions made in the EIS.

Comment 71 *Page 4-26, "Rocky Reach Dam", 2nd sentence. The text reads "As with the fishways at the Wells Dam, there is evidence to suggest that sockeye and summer-run chinook salmon experience passage delays in the fishway entrance pools of the Rocky Reach fishway." What is the citation for this information? The District is not aware of this information.*

Response 71 The FEIS was changed to cite Stuehrenberg et al. (1994) to support these statements.

Comment 72 *Page 4-27, Section 4.2.2.3 "Pacific Lamprey", 3rd sentence. The text reads "The only screens that are currently in operation at the Mid-Columbia River dams are at turbine units one through three at the Rocky Reach Dam." This is not correct. Screens are used only at turbine units one and two at the Rocky Reach Dam.*

Response 72 Text was modified in the FEIS to reflect the comment.

Comment 73 *Page 4-27, Section 4.2.2.3 "Pacific Lamprey", 4th sentence. Delete the phrase "although additional screens are currently not planned for future installation."*

Response 73 Text was deleted in the FEIS.

Comment 74 *Page 4-31, "Adult Migration/Survival", 2nd paragraph last sentence. The text reads "Although the radio-telemetry technique is problematic for addressing adult passage survival, the study results are the best available data for determining potential project related affects." This sentence is not correct. Radio-telemetry is not a technique for addressing adult passage survival. It is a technique for addressing locations of adult fish. Currently, no protocol exists to measure adult survival. There is no data available to evaluate adult survival.*

Response 74 See response to CCPUD Comment #64.

Comment 75 *Page 4-31, "Adult Migration/Survival", 4th paragraph, 2nd sentence. The text reads "Based on their presence at the project and their migratory behaviors, it is likely that some portion of the population passes through the turbines and spillways, either voluntarily or involuntarily." What is the citation for this information? Why is it reasonable to assume a correlation between presence of bull trout in the fishway and bull trout passing through turbines and spillways? The District is aware of no evidence supporting this statement.*

Response 75 The draft report *Movements of Bull Trout Within the Mid-Columbia River and Tributaries 2001-2001* by BioAnalysts, Inc. supports the assumptions made in the EIS.

Comment 76 *Page 4-34, "Rock Island Dam", 1st paragraph, 1st sentence. Delete "chiwawa hatchery". Rock Island's hatchery is referred to as the Eastbank Hatchery Complex.*

Response 76 Text was modified in the FEIS to reflect the comment.

Comment 77 *Page 4-40 "Rocky Reach Dam", 2nd paragraph, 3rd sentence, and Page 4-41 "Rock Island", 2nd paragraph 3rd sentence. The text reads "For Alternative 3, the PUD would have the ultimate authority for determining the appropriate protection measures implemented in Phase I, while the Coordinating Committee would have a greater role during Phase II." As explained above in relation to other sections, the Coordinating Committee is the decision maker in Phase II. NMFS has retained the authority to enforce the incidental take permit outside the HCPs.*

Response 77 This comment is no longer relevant with the language in the revised HCPs. See NMFS responses to DEIS public comments, Appendix C, Responses #18 and #22.

Comment 78 *Page 4-59, Section 4.6.3.1 "Project Area". This text is not correct. Section V of the HCP titled "Reservoir as Habitat" clarifies the manner in which land use and permitting decisions on project lands occurs.*

Response 78 Text was added to the FEIS to clarify.

Comment 79 *Page 4-72, Section 4.10.7 "Indian Trust Assets", 3rd paragraph, 5th sentence. The text reads "This would then affect whether the 9 percent no net impact would continue over the 50 year HCP terms." Reduction in use of the hatchery facilities means that the hatcheries would not produce fish to compensate for the full 7 percent of Unavoidable Project Mortality. HCP Section III.1. Nevertheless, No Net Impact can still be achieved as long as the PUDs provide the funding and capacity for the hatcheries. HCP Sections III.3. and 4.*

Response 79 Text was modified in the FEIS to reflect the comment. See NMFS responses to DEIS public comments, Appendix C, Response #17.

Comment 80 *Page 4-74, Section 4.10.14.1 "Wild and Scenic River Act". This section needs to be updated. On June 9, 2000, the Hanford Reach was declared a National Monument. 65 Federal Register 37253 (June 13, 2000).*

Response 80 Text was added to the FEIS.

Comment 81 *Page 5-6, Chelan County PUD 2000 reference. The District objects to reference to comments provided to the "Pre-Decisional Review Draft, Biological Opinion, Interim Protection Plans for Operation of the Mid-Columbia River Hydroelectric Projects and Related Activities." These comments were provided to assist in editing a confidential, pre-decisional review document.*

Response 81 Text was deleted from the FEIS.

Comment 82 *Page 6-1 "Glossary". It is the District's understanding that the glossary contained in the DEIS is not in any way intended to modify terms that are defined in the Endangered Species Act, NMFS's regulations, or the HCPs. The District has not reviewed the glossary, and reserves the right to latter object to the manner in which terms are defined in this DEIS.*

Response 82 Comment noted.

Comment 83 *Page 7-2, Section 7.3. Add the following local agencies: East Wenatchee Chamber of Commerce, Mayor of the City of Wenatchee, Chelan County Commissioners, and the Douglas County Commissioners.*

Response 83 The listed local agencies were added to the FEIS.

Comment 84 *Page 7-2, Section 7.4. Replace "Confederated Tribes of the Colville Reservation" with "Confederated Tribes and Bands of the Colville Indian Reservation." In the Umatilla name add "Indian" between "Umatilla" and "Reservation." Replace "Yakama Indian Nation" with "Confederated Tribes and Bands of the Yakama Indian Nation."*

Response 84 Text was modified in the FEIS to reflect the comment.

Re: Draft Environmental Impact Statement regarding the proposed Anadromous Fish Agreements and Habitat Conservation Plans for the Wells, Rocky Reach and Rock Island Hydroelectric Projects.

Dear Mr. Dach:

Public Utility District No.1 of Douglas County, Washington (Douglas PUD) has reviewed the Draft Environmental Impact Statement regarding the proposed Anadromous Fish Agreement and Habitat Conservation Plans (HCPs) for the Wells, Rocky Reach and Rock Island Hydroelectric Projects and provides the attached comments for your consideration.

Douglas PUD appreciates the NMFS collaborative effort to accurately describe the complex set of guidelines established in the Wells Habitat Conservation Plan (HCP) Implementation Agreement. In general, the Draft Environmental Impact Statement (EIS) for the proposed Anadromous Fish Agreements and Habitat Conservation Plans, released on December 29, 2000, is a fair and adequate presentation of the negotiated Wells HCP. Due to the complex nature of this and related documents, it is no surprise that additional comments and suggested revisions are being submitted prior to the adoption of the final Environmental Impact Statement.

If you have any questions concerning Douglas PUD's comments, please feel free to contact me at (509) 884-7191.

Sincerely,

Robert W. Clubb, Ph.D.
Chief of Environmental and Regulatory Services

c. Susan Fruchter, NEPA Coordinator

Public Utility District No.1 of Douglas County
Comments to Draft Environmental Impact Statement
April 30, 2001

GENERAL COMMENTS

Douglas PUD appreciates the NMFS collaborative effort to accurately describe the complex set of guidelines established in the Wells Habitat Conservation Plan (HCP) Implementation Agreement. In general, the Draft Environmental Impact Statement (EIS) for the proposed Anadromous Fish Agreements and Habitat Conservation Plans, released on December 29, 2000, is a fair and adequate presentation of the negotiated Wells HCP. Due to the complex nature of this and related documents, it is no surprise that additional comments and suggested revisions are being submitted prior to the adoption of the final Environmental Impact Statement. Specific comments related to the draft EIS are included below.

SPECIFIC COMMENTS

1. **Page S-15, S.5.3 Alternative 3 (Applicants' Proposed Action – Project HCPs), second Paragraph, last Sentence.** We request further clarification regarding the following statement, "(EIS prepared by FERC including a separate Section 7 consultation with NMFS regarding the effects of the agreements on listed species)."

   This paragraph indicates that FERC needs to prepare a second EIS for implementation of the HCPs. The parties expended considerable effort prior to preparation of the Draft EIS to avoid this unnecessary duplication. There is no rationale for FERC to prepare a separate EIS to implement the HCP.

2. **Page S-22, Para. 1, line 5 and line 11.** Please change the following two statements, "If juvenile dam passage survival ..." to "If juvenile project passage survival ..."

3. **S-22, Para. 1, line 5.** "If juvenile dam passage survival after <u>three</u> years of evaluations remains..."

   The Wells Implementation Agreement specifically calls for three years of survival studies within the five-year period known as Phase I. Phase I began in 1998.

4. **Page S-29, Table S-2 Alternative Comparisons (Alternative 1).** In the section labeled, "Continued Studies to Assess Survival" please clarify that continued survival studies at Wells Dam toward the goal of determining passage survival conditions at Rock Island and Rock Reach dams is not the responsibility of the Wells Project owner.

5. **Page S-35, Second Column, second to last Bullet.** "determine whether the species can be expected to survive with an adequate potential for recovery under the proposed action,..." Please define "adequate potential" in terms of interim recovery goals and standards. Would a greater than 50% probability of recovery be sufficient?

   How does, "adequate potential for recovery" relate to the "not likely to jeopardize the continued existence" standard spelled out in Section 7 (a) (2) of the Endangered Species Act?

6. **Page S-38, Table S-3 Environmental Comparison of the Alternatives (Page 3 of 8).** Under *Fisheries Resources: Other Plan Species - Adult Reservoir Spawning,* Alternative 1, 2 and 3 are listed as being: "Same as discussed for threatened and endangered species above." However, under the T & E section (above) there is no discussion of Adult Reservoir Spawning.

7. **Page S-39, Table S-3 Environmental Comparison of the Alternatives (Page 4 of 8).** Under *Tributary Habitat Improvements* for Alternative 1, 2 and 3. Given that this document is intended to evaluate three possible environmental alternatives related to future operation of PUD dams, we are confused by the following statement: "Habitat improvements would occur through the implementation of non-PUD funded projects through Federal, State and local agency funding." This statement misleads the reviewer to conclude that habitat improvements will take place regardless of the selected alternative. Simply stated, under Alternative 1 and 2 the PUDs would not fund off-site habitat improvements. Under Alternative 3 the PUDs would fund tributary enhancement toward a 2% increase in survival per project for plan species covered by the HCP. Under all three alternatives the agencies may pursue habitat improvements.

8. **Page S-40, Table S-3 Environmental Comparison of the Alternatives (Page 5 of 8). Alternative 1, Water Quality, Tributary Water Quality.** We suggest removing references to agency-funded habitat work. The inclusion of agency funding of habitat projects only confuses the three environmental options being evaluated. Under Alternative 1 and 2 the PUDs would not voluntarily fund improvements in water quality in the tributaries. Under Alternative 3, the PUDs would voluntarily provide direct funding toward the improvement of tributary water quality. This clear distinction needs to be drawn between the three Alternatives.

9. **Page S-40 and S-43. Table S-3 Environmental Comparison of the Alternatives (Page 5, 6, 7 & 8).** Actions common to all three alternatives and outside the control of the decision related to the EIS should not be presented in this table. Similarly, the actions referred to under **Comment #8** should also be applied to statements contained under subsections: Vegetation (Project Area, Associated Tributaries), Wildlife (Threatened and Endangered Species), Land Use (Associated Tributaries), Economics (Tributary Habitat Improvement), Recreation (Tributary Habitat Improvements, Columbia River System) and Cultural Resources (Tributaries).

10. **Page 1-6 and 1-7. 1.5.2.1 Endangered Species Act Requirements for Non-Federal Actions. "The No Surprises Policy and Adaptive Management"** These two policies appear to be in conflict when it comes to implementation under the proposed HCP. Please describe how conflicts between the two policies will be mediated during the implementation of Alternative 3.

11. **Page 1-16. 1.6.3 Alternative 3 (Proposed Action), first Bullet on Page 1-16.** Please modify the following statement: "evaluate project specific survival rates," to "evaluate project specific juvenile survival rates."

12. **Page 1-32, 1.10 Background Summary, second Paragraph, second Sentence.** "Therefore, this EIS is being developed for the purpose...whether or not to issue incidental take permits." This statement appears to conflict with the statement made on **Page S - 15** and **Page 2-32.** The EIS purpose includes amendment of FERC licenses. For a further description of our concerns please see Comment No. 1.

13. **Page 2-14, Wells Dam, second column of text, last Sentence of text in the first partial paragraph.** We take issue with the following statement: "Therefore, the total direct and indirect mortality is likely similar to the 2 percent found at the lower Snake River project bypass systems (NMFS 1998)." We disagree. The Wells bypass system is not similar to the Snake River screen bypass systems. The Wells system performance is superior to those found at the lower Snake River projects. Survival assigned to this passage route should be similar to the estimated survival assigned to spillway passage routes.

    In contrast, the Snake River screen bypass systems utilize extensive turbine intake screens, small gatewell orifice passages, collection channel dewatering, dewatering in transport pipes, handling and delay in sampling facilities, and reintroduction back into the tailraces through low volume pipes located immediately adjacent to predator-plagued shorelines.

    The Wells surface collection system does not utilize massive intake screens, orifice passageways, transportation pipes, handling facilities and low water tailrace discharges. The Wells surface collector guides fish away from the turbines and into the spillways where five high volume non-turbine passage routes are provided through the dam. Fish are introduced back into the tailrace turbine discharge where velocities are sufficiently high to prevent predator accumulation and where gull wires protect fish from avian predators.

    We suggest using a combined estimate of direct and indirect mortality that ranges from 0% to 1% for the Wells surface bypass system.

14. **Page 2-17, 2.2.3.2 Adult Passage, second full Paragraph, first Sentence.** Please modify the following statement: "Survival rates of adult salmon and steelhead passing through the Mid-Columbia River has not been estimated due to insufficient radio-telemetry data." to "Survival rates of adult salmon and steelhead passing through the Mid-Columbia River have not been estimated due to an inability to differentiate tag loss, tag failure and fish loss." It is not presently possible to estimate adult survival in a statistically defensible manner with the present radio-telemetry technology.

15. **Page 2-23, Measures Planned, fourth Line.** Please replace "negotiations" with "agreements."

16. **Page 2-23, Measures Planned. 1. Adult Passage.**

    c. The Wells Settlement Agreement does not contain language that obligates the District to conduct modeling in the adult fishways.

    e. The Wells Settlement Agreement does not include conditions to continuously operate the juvenile surface bypass system from April through August for adult fallback and adult downstream passage.

17. **Page 2-23, Measures Planned. 2. Juvenile Passage. a.** The Wells Settlement Agreement does not contain requirements to operate the turbines at peak efficiency ratings.

18. **Page 2-23 and 2-24, Measures Planned. 2. Juvenile Passage. b. Surface Bypass Operation -** Please modify the following statement: "Operate at least one spillway bypass, 24-hours per day, throughout the juvenile downstream migration periods" to "Operate at least one spillway bypass, 24-hours per day, throughout 80% and 70% of the peak spring and peak summer juvenile downstream migration, respectively..."

19. **Page 2-24, Measures Planned. 2. Juvenile Passage.**

    c. **Predators and d. Gas Abatement.** Neither of these actions are outlined in the Wells Settlement Agreement. Please remove the statements from the EIS.

20. **Page 2-25, 2.3.1.2 Rocky Reach Hydroelectric Project.** Analogous sections are missing under Rocky Reach and Rock Island project descriptions that are present under the Wells Project description. Please add the following Section designations to the Rocky Reach and Rock Island Project descriptions to allow a more rigorous comparison of actions proposed at different projects: Adult Fish Passage, Juvenile Fish Passage, Hatchery Based Compensation, and Monitoring and Evaluation.

21. **Page 2-28, second full Paragraph, fifth Line.** The QAR analysis findings that, "even the removal of the Mid-Columbia River dams would not be sufficient to recover these species, if recent total life history survival rates continue," should be expressed in the Summary on **Page S-16, S.5.3.2 HCP Baseline Conditions.**

22. **Page 2.29, 2.3.2.1 Wells Hydroelectric Project. 3. Hatchery Program -** It is important to point out that under Alternative 1, 2 and 3, Douglas PUD has

the ability to reduce hatchery production (including summer and spring chinook, steelhead, and sockeye) based upon the results of survival studies. Also, under Alternative 2 and 3, NMFS has the authority to reduce or modify hatchery production of listed and non-listed species to remain consistent with their long-term recovery strategies for listed Upper Columbia River spring-run chinook and summer-run steelhead.

23. **Page 2.35, 2.3.3.5 HCP Performance Standards, third full Paragraph, last Sentence.** "In addition, the 91 percent survival standard also includes reservoir survival and the dam passage survival of returning adults." This statement is inaccurate as presented. The HCP was set up to measure 91% juvenile project passage survival. The 91% juvenile number was derived by assuming loss of adults (2%), assuming loss through the reservoir (2%) in addition to the 5% allowed loss at the dam. Further assumptions related to the 91% determination included an assumed 2% delayed mortality from hydro passage and a 2% credit for natural river fish loss.

    The agreement reached on the HCP does not include measurement of adult survival at a 95% CI +/- 5%. This is evident from the adult language in the implementation agreement, the timeline for completion of the Phase I studies (5 years) and based upon the knowledge that precise adult survival studies were not statistically or scientifically defensible at the time the Implementation Agreement was negotiated. The PUDs did not sign up to ensure adult survival from tailrace to tailrace at a rate of 98% irrespective of natural mortality.

    It is important to point out that during the negotiations of the HCP, a 2% adult mortality figure was discussed. However, the final HCP Implementation Agreement was approved without referencing the measurement of the 2% adult mortality figure. The final agreement says "...and a net of 4% mortality from all other project effects (including but not limited to reservoir, juvenile delay, and adult mortality with credit for natural mortality)." Please remove all discussion that indicates the HCP has a 2% measurable adult mortality component.

24. **Page 2.41, Verification of Standards.** We agree with the statements in the first and second paragraphs of this section related to the verification of standards.

25. **Page 2-56, Table 2-8 Environmental Comparison of the Alternatives (Pages 1 of 8).** Please modify this table per similar concerns expressed in comment No. 7, 8 and 9. The DEIS is intended to compare actions related to the implementation of three environmental alternatives for fish mitigation at three FERC licensed projects (No action, S. 7 and HCP). Descriptions of actions outside those proposed by the PUDs (agency-funded habitat enhancement actions) should be removed from the document.

26. **Page 2-56, Table 2-8 Environmental Comparison of the Alternatives (Pages 1 of 8), juvenile migration/survival standards.** Please change, "project specific standards" under Alt. 1 to "Project specific fish passage standards."

27. **Page 2-59, Table 2-8 Environmental Comparison of the Alternatives (Pages 4 of 8), Drawdown, Alt. 2.** It should be mentioned that drawdown under Alternative 2 could only be considered during relicensing of the projects.

28. **Page 3-10, Figure 3-4 Geology of the Rock Island Dam Area.** There are two identical categories for Grande Ronde Basalt. What is the difference between N2 and R2 Units? In the figure, there is no discernable difference between the two geological formations.

29. **Page 3-28, Steelhead, Line 2.** Please modify the following statement: "Rock Island Dam averaged 2,600 to 3,700 fish" to "Rock Island Dam ranged from 2,600 to 3,700 fish." The same comment applies to Line 4 of this same paragraph.

30. **Page 3-28, Sockeye Salmon.** Please standardize the years being compared to 10-year intervals. As presented, the intervals appear to be contrived to show a recent decline in numbers of sockeye passing Rock Island Dam.

31. **Page 3-29, Coho Salmon, Last sentence.** This section should also note the release of millions of coho by Chelan PUD at the Turtle Rock Hatchery. This facility continued to release coho through the mid - 1980's.

Note that coho ladder counts at Rock Island totaled only 475 fish between 1933 and 1943 (Mullan, 1983; Mullan et al., 1992). That is an average of less than 48 fish per year. The statement: "After completion of Priest Rapids Dam in 1960, peak escapement estimates probably never exceeded 10,000 fish" is misleading. The statement should be modified to indicate that few coho existed prior to the completion of Grand Coulee and Rock Island dams. The statement subtly implies a cause and effect relationship between the completion of Priest Rapids Dam and the demise of the coho run. The Upper Columbia River coho run had already been wiped out prior to construction of any mainstem Columbia River dams as is evident from fishway counts immediately following the completion of Rock Island Dam.

32. **Page 3-29, Table 3-1 Spawning Distribution of Anadromous Fish Species in the Mid-Columbia River Watersheds.** Fulton (1968) appears to incompletely describe salmon and steelhead spawning in the Mid-Columbia Region. Please modify Table 3-1 to include the distribution of fish described below.

Fall Chinook - Please add the Columbia and Methow rivers to the watersheds utilized extensively by Fall Chinook.

Steelhead - Please add the Twisp and Chewuch rivers and Libby Creek as being important Methow River tributaries for spawning steelhead. It should be noted that Salmon and Omak creeks are not presently important steelhead habitats. "Simikameen" is spelled "Similkameen." Also note, steelhead do not have access to the Upper Similkameen River. Instead they only have access to the Lower Similkameen River. Enloe Falls blocks steelhead access to the Upper Similkameen River.

Sockeye - Extensive spawning ground surveys for sockeye have not resulted in documented sockeye spawning in the mainstem Okanogan River. Please remove the reference to the Mainstem Okanogan River as a tributary of the Okanogan River used by spawning sockeye. Please modify the sentence to state that the Osoyoos Lake sockeye population is almost entirely spawned in the Okanogan River, upstream of Osoyoos Lake.

33. **Page 3-30, 3.2.3 Tributary and Mainstem Development, end of first Paragraph.** The last statement in this paragraph is not entirely accurate. Hydroelectric facilities on the Cowlitz, Lewis and Willamette rivers do not all contain adult fish passage facilities. Some transport fish by truck upstream of the projects and others are migrational blocks to migrating adult salmon and steelhead. Please modify the statement to read: "All mainsteam Columbia and Snake river dams downstream of these projects are equipped with facilities to allow ..."

34. **3.2.4 Hatchery Programs, Page 3-31, First line on page 3-31.** Please modify the percent of summer-run chinook salmon that are of hatchery origin in the Mid-Columbia River. 80% hatchery composition for this stock is not accurate. The following table indicates the best estimate of hatchery contribution for the watersheds covered by this EIS (Table 1). The hatchery contribution of fall chinook is also closer to 20-30% and not 50%.

Table 1: Escapement to the Wenatchee, Methow and Okanogan rivers of hatchery origin summer chinook (Table adapted from Murdoch and Petersen, 2000).

Return Year	Wenatchee	Methow	Okanogan
1991	2.4	0.0	0.0
1992	1.5	0.0	3.5
1993	5.0	24.0	36.1
1994	12.0	45.0	48.7
1995	9.2	36.9	54.6
1996	4.9	15.8	59.3
1997	8.5	9.2	54.3
1998	10.7	22.2	29.9

Murdoch, A. and K. Petersen. 2000. Survival of sockeye, spring chinook, and summer chinook salmon released from Rock Island Fish Hatchery Complex Facilities, 1989 through 1995 broods. Prepared for Public Utility District No. 1 of Chelan County. Washington Department of Fish and Wildlife, 600 Capitol Way N., Olympia, Washington 98501-1091.

35. **Page 3-31, 3.2.4.2 Hatchery Compensation for Mid-Columbia Tributary Losses.** There is no plan in place to compensate for Mid-Columbia Tributary Losses. Please replace, "Tributary Losses" with "Mainstem Passage Losses."

36. **Page 3-37, Rocky Reach, second Paragraph in section, last Line.** There was no sockeye salmon passage study at Rocky Reach in 1993. The 1993

study was a chinook study. There was a sockeye passage study at Wells Dam in 1992. However, this study did not include any monitoring at Rocky Reach Dam. The 14% fallback estimate was derived from the 1997 sockeye monitoring effort only (English et al., 1998).

37. **Page 3-38, Rock Island Dam, second Paragraph, first Line.** There was no sockeye study at Rock Island Dam in 1993.

38. **Page 3-42, 3.2.6.3 Juvenile Bypass Systems, Wells Dam, second Paragraph, last Sentence.** We disagree with the assertion that the Wells bypass system likely has indirect mortality similar to the diversion screen bypass systems located at the Snake River projects. See Comment No. 13 for the rationale for not comparing the Wells Bypass system to the Snake River bypass systems.

    The Wells bypass system is a highly efficient spill bypass system. Indirect mortality resulting from passage through this system should be compared with indirect mortality estimates derived from spillway survival studies.

39. **Page 3-46, Rocky Reach, second Paragraph, last Sentence.** The yearling fall-run chinook survival studies cited in this paragraph were conducted in 1998 not 1999. Also, the results from the Eppard et al. (1999) study were not accurately cited. Eppard et al. (1999) provides two estimates of Rocky Reach survival from yearling chinook release in 1998. Table 10, Page 38 of the report states Rocky Reach project survival, depending upon the model selected, as (0.867, $\hat{SE} = 0.065$) based upon the parallel SR Model and (0.859, $\hat{SE} = 0.042$) based upon the PR model.

40. **Page 3-65, Icicle Creek.** The 19 miles of historical habitat is disputed by USFWS personnel stationed in Leavenworth. Radio-telemetry studies conducted in 2000 by the USFWS indicated that a natural obstruction in the river restricted fish access into the upper watershed. The obstruction is located within the first 3 miles of river upstream of the existing barrier dam.

41. **Page 3-72, Summer/Fall-Run Chinook Salmon, first Paragraph, eighth Line.** We suggest the following modification to the defined spawning distribution of summer chinook in the Methow River. Summer chinook have been observed spawning downstream of French Creek near the mouth of the Methow River immediately upstream of the town of Pateros. This expands the spawning distribution from 38 to 42 miles of habitat.

42. **Page 3-72, Steelhead, ninth Line.** Please modify the following statement, "Spawning occurs primarily in late March, but may extend into July." to "Spawning is initiated as early as late March and can extend into July." Based upon surveys conducted in 1999, peak steelhead spawning appears to be taking place in late April rather than late March.

43. **Page 3-74, Top of page, first partial Paragraph, last Sentence.** The abandonment of planting catchable rainbow was intended to reduce incidental harvest on steelhead smolts although it likely also protects a lesser number of chinook salmon smolts. Please add steelhead smolts to the list of species whose incidental harvest has been reduced by the cessation of planting catchable rainbow trout.

44. **Page 3-74, Riparian and Stream Channel Condition, forth Paragraph, second sentence.** Please modify the second sentence to state, "Ironically, the areas most susceptible to dewatering by low flow events are often the areas containing the highest..."

45. **Page 3-76, Fish Resources, line seven.** Observations of bull trout in the Okanogan Watershed have been limited in recent history. We suggest removing bull trout as an "important" fish resource in the Okanogan Basin. This suggested change is consistent with surveys conducted by the USFS, Okanogan National Forest and conclusions reached in *Washington State, Limiting Factors Analysis for the Okanogan River Watershed.*

46. **Page 3-77, Habitat Condition, first Paragraph, last Sentence.** Please change, "The Wells Dam pool inundates the lower 17 miles of the Okanogan River." to "The Wells project boundary includes the lower 17 miles of the Okanogan River."

During normal operation, the Wells Project does not inundate the entire 17 miles of the lower Okanogan River. The Wells Project boundary was drawn to encompass possible inundated lands during a worst-case scenario flood event. In effect Douglas PUD has the right to inundate the lower 17 miles of the Okanogan River only during times when the Columbia and Okanogan rivers experience a simultaneous 100-year flood event that for some reason might not be mitigated through storage at Grand Coulee and the Canadian Treaty Storage Projects.

47. **3.3.1.1 Project Area, Page 3-83, Wells Dam, Rocky Reach and Rock Island Dam.** Please standardize the months that average flows are compared between projects. We would recommend using June and September rather than using a mixture of months. Also note that average September flows referenced for Wells Dam (114,791 cfs) is much higher than the average September flows cited at Rock Island Dam (74,478 cfs). Given that Rock Island Dam is downstream of Wells Dam and that the Chelan, Entiat and Wenatchee rivers all enter the Columbia River between Wells and Rock Island Dam, these averages appear to be incorrect. Average September flows at Wells Dam should be slightly less than the average September flows at Rock Island Dam.

48. **Page 3-84, Figure 3-5, Average Monthly Flows (cfs) in the Mid-Columbia River at Wells Dam.** Average September flows at Wells Dam appear to be less than 80,000 cfs.

49. **Page 3-85 & Page 3-83, Figure 3-6, Average Monthly Flows (cfs) in the Mid-Columbia River at Rocky Reach Dam.** According to the Figure, average June flows at Rocky Reach are in excess of 150,000 cfs not 136,147 cfs as cited on page 3-83.

50. **Page 3-87, Wenatchee River, first Paragraph, line 6.** The Wenatchee River watershed drains 1,328 square miles not 1.328 square miles.

51. **Page 3-89, Entiat River, second Paragraph, line five.** The maximum and minimum average monthly flows for the Entiat River are incorrect. Both numbers presented in the report do not match with USGS information and are highly unlikely given that the reported numbers exceed those of the Wenatchee and Methow Rivers.

    Please see Figure 3-9. The average monthly flows from this figure indicate that the Entiat River in June averages less than 1,800 cfs and in September averages less than 200 cfs. Please reconcile the text and Figure 3-9.

52. **Page 3-87, 3-89 & 3-91.** Please standardize the average monthly flows being reported for the various tributary streams.

53. **Page 3-91, Okanogan River, second Paragraph, last Sentence.** Please see Comment No. 46.

54. **Page 3-97, Wells Dam, first and second Paragraph.** The temperature excursion cited at the Columbia River at the Wells Hatchery intake is in error. The water temperatures reported here were not collected at the hatchery intake but were collected from the hatchery spawning channel after water had been held in shallow ponds immediately downstream of the intake of the facility. Also, the readings were not collected from a systematic, calibrated subsurface monitor but were instead collected with a non-calibrated, hand-held thermometer, sporadically used to collect relative water temperatures by fish culture staff stationed at the Wells Fish Hatchery.

    Note that the mainstem Columbia River water quality data collected immediately downstream of Wells Dam (Chelan Falls) does not show water temperate excursions above the criteria established for state waters.

55. **Page 4-1, 4.1.1.2 Associated Tributaries, first, second and third Paragraphs, (Alt. 1).** This entire section should be deleted and re-written with emphasis on contrasting the three proposed environmental alternatives. Describing additional actions outside the three alternatives that may be funded regardless of the outcome of the HCP only confuses readers. This comment is similar to Comments No. 7, 8 and 9.

    We suggest changing this section to describe the fact that under the No-Action alternative, no PUD tributary enhancement funds would be available. The agencies are free to spend money on habitat improvements common to all three alternatives so this entire section (4.1.1.2) provides no information related to the decision to select one of the three proposed alternatives.

    This comment also applies to **Page 4-3, 4.1.2.2 Associated Tributaries.**

56. **Page 4-6, second full Paragraph, second Line.** It is important to point out that drawdown is not an option under the No Action Alternative (Alternative 1). It could be an option that is discussed through relicensing of the projects (Alternative 2) or by unanimous consent of the HCP signature parties under Alternative 3.

57. **Page 4-17, Wells Dam, second bullet.** Under Alternative 1, the District is not obligated in the Wells Settlement Agreement to operate the bypass system 24-hours per day during the period that encompasses 95% of the downstream migration.

58. **Off-Site Mitigation, Page 4-43, first Paragraph.** Please add that the proposed Douglas HCP has a provision that if juvenile project survival is greater than 95%, the tributary funding package would be reduced from 2% to 1%. This comment also applies to the section titled: **Tributary Habitat Improvements** found on **Page 4-43**.

59. **Page 4-65.** Please modify "4.9.2.1 Project Are" to "4.9.2.1 Project Area."

Re: Draft Environmental Impact Statement (DEIS) for the Habitat Conservation Plans proposed for Public Utility District No. 1 of Douglas County, Washington, and the Public Utility District No. 1 of Chelan County, Washington, 65 *Federal Register* 82976 (Dec. 29, 2000), as amended by 66 *Federal Register* 2903 (Jan. 12, 2001)

Dear NMFS:

Public Utility District No. 1 of Chelan County, Washington (the "District") appreciates this opportunity to comment on the Draft Environmental Impact Statement for the Habitat Conservation Plans proposed for Public Utility District No. 1 of Douglas County, Washington, and Public Utility District No. 1 of Chelan County, Washington (the "DEIS").[1]

We appreciate this first major step in the regulator review of the District's incidental take permit applications.[2] However, we have a number of concerns. First, we are very disappointed in the amount of time it has taken to reach this step. The District's incidental take permit applications were filed with NMFS on July 30, 1998. At NMFS instance, the District along with Public Utility District No. 1 of Douglas County have funded Parametrix, Inc. since 1998 to expedite NMFS' regulatory review of the incidental take permit applications. The District promised a two-year regulatory review

[1] 65 *Federal Register* 82976 (Dec. 29, 2000), as amended by 66 *Federal Register* 2903 (Jan. 12, 2001).
[2] Application for Individual Incidental Take Permit for the Rocky Reach Hydroelectric Project, FERC No. 2145 (July 30, 1998); Application for Individual Incidental Take Permit for the Rock Island Hydroelectric Project, FERC NO. 945 (July 30, 1998).

process in consideration for funding NMFS' contractor. We have not received expedited treatment.

Second, the DEIS does provide a clear explanation of the Anadromous Fish Agreements and Habitat Conservation Plans (the "Agreements") upon which the incidental take permit applications are based. As a result the Agreements cannot be fully compared with the other alternatives, and the analysis of the Agreements is not complete or accurate. To address the second problem, the District's comments start with a summary and interpretation of the Agreements. In this section the District provides, for the benefit of NMFS and the general public, a general summary of how the Agreements should be interpreted.

Third, as pointed out in the Specific Comments, there are several instances where NMFS misstates data. This provides a skewed view of how the Agreements will work, and how the Agreements compare with other alternatives. Of greatest concern is NMFS continued reliance upon the Quantitative Analytical Report (the "QAR"). The QAR is another processes the District and Public Utility District No. 1 of Douglas County, Washington were forced to fund to expedite review of the Agreements. In consideration for funding the QAR, NMFS promised that the QAR would be a fair, open and scientific process.

The QAR should not be included in the DEIS. NMFS has kept the QAR internal to NMFS. The QAR is not final or peer reviewed. The District has not had an opportunity to view the QAR, yet NMFS heavily relies upon the QAR throughout the DEIS. As a result, neither the District nor the public can evaluate the DEIS with the QAR. Furthermore, based upon the District's limited knowledge of the QAR the QAR is severely mischaracterized in the DEIS.

Fourth, again as pointed out in the Specific Comments, the District continues its objection to NMFS' choice of alternatives. NEPA requires an environmental impact statement to review the proposed action with other measures. It is not appropriate for NMFS to compare regulatory review processes as alternatives in a DEIS.

It is the District's hope that NMFS will address the concerns we raise in these comments and amend the DEIS accordingly.

Summary of the Agreements

On July 30, 1998, the District submitted incidental take permit applications to NMFS for the Rocky Reach and Rock Island Hydroelectric Projects (the "Projects"). The incidental take permit applications are based upon proposed Anadromous Fish Agreements and Habitat Conservation Plans (the "Agreements"). The Agreements are

"intended to constitute a comprehensive and long term adaptive management plan for Plan Species[3] and their habitat as affected by the Projects."[4] They are unlike any other habitat conservation plan ever filed with the United States Fish and Wildlife Service or the National Marine Fisheries Services.

The Agreements are revolutionary due to their scope and management plan. The Agreements are titled Anadromous Fish Agreements and Habitat Conservation Plans and not just habitat conservation plans because they address more than just the Endangered Species Act. They also address Federal Power Act, the Fish and Wildlife Coordination Act, the Pacific Northwest Electric Power Planning and Conservation Act, the Clean Water Act and Title 77 of the Revised Code of Washington in one comprehensive agreement for each Project.

Because the Agreements are comprehensive settlements, they propose a standard greater than that required under the Endangered Species Act. The Agreements establish a survival standard of 100% No Net Impact ("NNI") which means that the Projects appear invisible to the species migrating past the Projects. There are two basic components of NNI. First, to protect the species migrating past the Projects, the Agreements establish a series of performance standards based upon the actual survival of the species, not simply measures to be implemented regardless of their actual benefit to the species. Second, all unavoidable mortality is mitigated. This occurs though tributary habitat improvements and through state of the art hatchery supplementation. Central to the Agreements are the processes for making decisions and resolving disputes. All the stakeholders that sign the Agreements make the decisions, and disputes can be resolved in as little as 16 days. These Agreements actually protect the survival of the salmon and restore their habitat.

The level of protection afforded in the Agreements is provided to not just listed Upper Columbia River steelhead and Upper Columbia River spring chinook. It also protects all other species of salmon migrating past the Projects; even coho salmon which are extinct from the Upper Columbia River, but are being re-introduced by the Confederated Tribes and Bands of the Yakama Indian Nation (the "Yakama Indian Nation").

The Agreements are the result of an extensive collaborative process dating back to 1993, and represent the collective wisdom and professional judgment of the scientists and regional policy makers of the NMFS, the United States Fish and Wildlife Service, the Washington Department of Fish and Wildlife, the Confederated Tribes and Bands of the

[3] Plan Species are defined as spring, summer and fall chinook salmon (*Oncorhynchus kisutch*), sockeye salmon (*O. nerka*), coho salmon (*O. kisutch*), and steelhead (*O. mykiss*). Rocky Reach at Section XII.11; Rock Island at Section XII.11.

[4] Rocky Reach, Introduction, Paragraph A.; Rock Island, Introduction, Paragraph A.

Colville Indian Reservation, the Yakama Indian Nation, the Confederated Tribes of the Umatilla Indian Reservation, and American Rivers, Inc. participating in the process.

The Agreements

To assist in understanding the Rocky Reach and Rock Island Anadromous Fish Agreements and Habitat Conservation Plans, the District provides the following summary and interpretation of the Agreements.

What species are protected?

The Agreements apply to anadromous salmonids, known as the "Plan Species."[5] Plan Species are defined as spring, summer and fall chinook salmon (*Oncorhynchus kisutch*), sockeye salmon (*O. nerka*), coho salmon (*O. kisutch*), and steelhead (*O. mykiss*).[6] However, since coho salmon are extinct in the portion of the Columbia River affected by the Projects, the District did not request that the incidental take permit apply to coho salmon. The sub-set of the plan species for which the incidental take permits are requested are referred to in the Agreement as the "Permit Species."

What is the biological plan? (the standards)

The Survival Standards. The objective of the Agreements is to achieve 100% No Net Impact for each Plan Species affected by the Projects.[7] NNI consists of two components: (1) 91% Project Survival achieved within the geographic area of each Project by project improvement measures, including an independent standard of 95% Juvenile Dam Passage Survival; and (2) 9% compensation for Unavoidable Project Mortality provided through hatchery and tributary programs, with 7% compensation provided through hatchery programs and 2% compensation provided through tributary programs.[8] NNI will be maintained for the duration of the Agreement for each Plan Species affected by the Project. A coordinating committee composed of each entity that signs the Agreements will ensure the NNI is achieved and maintained by: (1) overseeing monitoring and evaluation, and (2) periodically adjusting the measures being implemented to address actual project survival and compensate for all unavoidable project mortality.[9]

---

[5] Anadromous Fish Agreement and Habitat Conservation Plan Rocky Reach Hydroelectric Project, FERC No. 2145 (Rocky Reach), Section XII.1; Anadromous Fish Agreement and Habitat Conservation Plan Rock Island Hydroelectric Project, FERC No. 943 (Rock Island), Section XII.1.
[6] Rocky Reach at Section XII.11.; Rock Island at Section XII.11.
[7] Rocky Reach, Introduction, Paragraph B; Rock Island, Introduction, Paragraph B.
[8] Rocky Reach at Section III.1.; Rock Island at Section III.1
[9] Rocky Reach at Section III.2.; Rock Island at Section III.2.

To achieve NNI, the District is obligated to achieve and maintain 91% Project Survival, which means that 91% of each Plan Species, juvenile and adult combined, survive Project effects, including delayed mortality wherever it may occur.[10] However, recognizing that the impacts associated with hydroelectric projects are focused at the concrete (the Dam) the Agreements require the District to achieve and maintain 95% Juvenile Dam Passage Survival, which means that 95% of the juvenile Plan Species over 95% of each species' migration survive the journey through the forebay, dam, and tailrace of each Project.[11]

There is one exception to the 95% Juvenile Dam Passage Survival standard. Provided that turbine intake screens are installed at the Dam, spring-migrating chinook salmon (*Oncorhynchus tshawytscha*) smaller than 50 mm in length will be excluded from 95% Juvenile Dam Passage Survival, but not from 91% Project Survival for the full run of that Plan Species.[12] This exception is necessary to account for the competing needs between species and choosing a way to best protect all the species.

The Project Survival standard must be achieved for juvenile and adult Plan Species. However, current technology does not exist to measure adult survival. But, during the term of the Agreements, the parties that developed the Agreements felt very comfortable that technology would be developed, sooner rather than later, to measure adult survival. Since the District was obligated to achieve and maintain the standard, all signatories to the Agreements have the incentive to develop the technology and have it implemented as soon as possible

Until adult survival can be measured, to insure that adults received the maximum protection practicable in a way that can be measured, the Agreements' Adult Passage Plan defines actions to be taken by the District to protect adults. The Agreements give high priority to adult survival in the achievement of 91% Project Survival for each Plan Species.[13] This means that the District must provide for adult as well as juvenile survival. The District has a variety of tools it may use to achieve the targeted survival rate. These tools include, but are not limited to, a requirement that adult passage systems at the Project will be maintained and operated according to the detailed fishway operating plan identified in the Agreements or to criteria developed through the coordinating committee.[14] Spill and turbine units will be operated in a manner that provides for adult passage while meeting the 95% Juvenile Dam Passage Survival rate.[15] Areas within the adult fish passage system which are identified by the coordinating committee as either

[10]Rocky Reach at Section IV.1.a.; Rock Island at Section IV.1.a.
[11] Rocky Reach at Section IV.1.a.; Rock Island at Section IV.1.a.
[12] Rocky Reach at Section IV.1.b.; Rock Island at Section IV.1.b.
[13] Rocky Reach at Section IV.2.b.; Rock Island at Section IV.2.b.
[14] Rocky Reach at Section IV.2.b.i.; Rock Island at Section IV.2.b.i.
[15] Rocky Reach at Section IV.2.b.ii.; Rock Island at Section IV.2.b.ii.

consistently out of criteria or where significant delay occurs will be modified as soon as feasible by the District.[16] The District will use best efforts to eliminate identified sources of adult injury and mortality during adult migration through the Dam.[17] In addition, the District will identify adult fallback rates at the dam, and the coordinating committee will identify a method to protect steelhead kelts at the Dam, and a reduction in fallback rates, mortalities, and protection of kelts will be factored into juvenile bypass and adult passage development and implementation and into Project operation decisions.[18]

If the District is unable to achieve 91% Project Survival, including achievement of 95% Juvenile Dam Passage Survival, then the District is obligated to consult with the coordinating committee to jointly seek a solution.[19] If a solution cannot be identified to achieve the standards, then any Party may take action to withdraw from the Agreements on the basis that it is impossible to achieve the standards in the Agreement, or take action under any other provision of the Agreement.[20]

Unavoidable Project Mortality. Since hydroelectric projects obstruct the waterways the salmon use to migrate there is some mortality that just cannot be eliminated. This mortality is addressed in the Agreements as "Unavoidable Project Mortality." Unavoidable Project Mortality is initially assumed to be 9%, based on several assumptions regarding Project impacts.[21] The word "initially" is very important. It is currently not possible to measure Unavoidable Project Mortality. The biologists and policy makers that developed the Agreements', in their best professional judgment, assumed juvenile dam passage mortality to be 5% and a net of 4% mortality for all other project effects. These include, but are not limited to, reservoir, juvenile delayed, and adult mortality with credit for natural mortality.[22] Since Unavoidable Project Mortality is an assumption, it is implicit within the Agreements that once technology is developed to measure these numbers it will be accurately established.[23] Since the Agreements do not assign responsibility to any one party to take on this responsibility, the responsibility lies with the coordinating committee as a whole. Since the Agreements provide for the assumption to be verified all signatories to the Agreements have the incentive to develop the technology and have it implemented as soon as possible. In the event Unavoidable Project Mortality is proven to be something other than 9%, then the coordinating committee must decide what action should be taken.[24]

[23] Rocky Reach at Sections III.2. and XII.19.; Rock Island at Section III.2. and XII.19.
[24] Rocky Reach at Section III.; Rock Island at Section III.

Until Unavoidable Project Mortality can be established, 9% Unavoidable Project Mortality is assumed to be correct.[25] Unavoidable Project Mortality is addressed through hatchery and tributary compensation, with 7% compensation provided through hatchery programs and 2% compensation provided through tributary programs[26]

Hatchery Compensation Plan. Hatchery compensation is provided by the Agreements' Hatchery Compensation Plan. The District will provide the necessary funding and capacity to meet the 7% hatchery compensation level set by the NNI, and operate the hatchery according to the terms developed by the other signatories to the Agreement (the "JFP" or "Joint Fisheries Parties"), the NMFS Section 10 incidental take permit, and in consultation with the Hatchery Committee.[27] The JFP are responsible for developing the plans and programs necessary to implement the Hatchery Compensation Plan.[28] This allocation of responsibility is significant in that NMFS's policy decisions regarding management of "wild" fish under the Endangered Species Act may not allow full utilization of the hatchery capacity provided by the District. If this occurs, then as long as the District has provided the hatchery capacity and remains able to fund hatchery operations, the District will be in full compliance with the Agreement and its incidental take permit. However, under the Agreement, hatchery production will never be reduced to zero without action by the Federal Energy Regulatory Commission because the Agreement allows for the production of hatchery fish to compensate for original Project inundation.[29]

The fact that NMFS can reduce hatchery capacity is the reason the tribes do not currently support the Agreements. This is where it is important to recognize the fact that the Agreements are comprehensive settlement agreements. The tribes' current position is that they require a guarantee from NMFS that throughout the term of the Agreements the hatcheries will be fully utilized before they are willing to resume support of the Agreements. It is only through increased numerical abundance of the Plan Species that the tribes can fully realize the value of their fishing rights. The tribes dispute NMFS' policy decision to treat hatchery fish differently from wild fish. In addition, the tribes argue that the numbers of fish to be produced by the Projects' hatcheries is so small they will not appreciably reduce the likelihood of the survival and recovery of the Plan Species in the wild. This view is shared by the District and many other parties that developed the Agreements. Nevertheless, since NMFS and the other parties that developed the Agreements are situated differently than the tribes, they can continue to support the Agreements in light of this objection.

[25] Rocky Reach at Section XII.19.; Rock Island at Section XII.19.
[26] Rocky Reach at Sections III.1. and III.2.; Rock Island at Section III.1. and III.2.
[27] Rocky Reach at Section VIII.2.; Rock Island at Section VIII.2.
[28] Rocky Reach at Section III.4.; Rock Island at Section III.4.
[29] Rocky Reach at Section VIII.3.; Rock Island at Section VIII.3.

The initial estimated hatchery production capacities for Plan Species needed to provide compensation for Unavoidable Project Mortality are based on a variety of factors. Those include average adult returns of plan species for a baseline period, a 7% compensation requirement, and baseline adult/smolt survival rates for existing mid-Columbia River hatcheries. The estimated initial production capacity will be adjusted over time to help achieve and maintain NNI. As changes occur in the average adult returns of Plan Species, and in adult/smolt survival rate from the hatchery production facilities the production capacity will change. However, as described above, the original inundation mitigation will not be reduced.[30]

Tributary Conservation Plan. The Tributary Plan will compensate for 2% of Unavoidable Project Mortality.[31] The Tributary Conservation Plan consists of the Agreement and Exhibit B "Tributary Compensation Plan Species Account Project Selection, Implementation, and Evaluation Plan."[32] Under the Tributary Plan, the District will provide a Plan Species Account to fund projects for the protection and restoration of Plan Species' habitat within the Columbia River watershed, and the Okanogan, Methow, Entiat and Wenatchee River watersheds.

The Tributary Plan will be managed by a Tributary Committee composed of one representative from each party that signs the Agreement. In order to achieve minimum costs and maximize the monies in the Plan Species Account, there will be one Tributary Committee that manages the Tributary Plans for the Wells, Rocky Reach and Rock Island Hydroelectric projects.[33] In addition, to assure that the maximum amount of money will be spent on actual projects, committee overhead costs cannot exceed $80,000 without the unanimous vote of the Tributary Committee.[34] Whenever feasible, projects selected by the Tributary Committee shall "take into consideration and be coordinated with other conservation plans or programs", and "whenever feasible, the Tributary Committee shall cost-share with other programs, seek matching funds, and 'piggy-back' programs onto other habitat efforts."[35] The District has spoken with the staff of the Northwest Power Planning Council and the Governor's Locke's Salmon Recovery Task force, and many other entities. All are eager to coordinate their habitat programs with the Agreements' Tributary Programs.

Land Use Decisions. When the District makes land use or related permit decisions on Project lands that affect reservoir habitat, the District must consider the cumulative

[30] Rocky Reach at Section VIII.3.; Rock Island at Section VIII.3.

[32] Rocky Reach at Section VII.1.; Rock Island at Section VII.1.
[33] Rocky Reach at Section VII.3.; Rock Island at Section VII.3.
[34] Rocky Reach at Section VII.4.a.; Rock Island at Section VII.4.a.
[35] Rocky Reach at Section VII.3.e.; Rock Island at Section VII.3.e.

impact effects in order to meet the conservation objectives of the Agreement, requirements of the FERC license, and other applicable laws and regulations. The District will also notify and consider comments from the Parties to the Agreement regarding land use permit application on Project owned lands.[36] Applicants to use or occupy Project lands or waters must be informed by the District that such use or occupation may result in an incidental take of an endangered or threatened species under the ESA, and may require advance authorization from NMFS or USFWS.[37]

Early Termination Mitigation. Lastly, if the incidental take permit issued by NMFS is terminated early, NMFS may require the District to mitigate for any past incidental take that has not been sufficiently mitigated prior to the termination of the permit. NMFS would require the District to continue relevant mitigation measures of the Agreement for some or all of the time period covered by the permit as originally issued.[38]

Thus, the combination of the Juvenile Dam Passage Survival and Project Survival standards coupled with the required spill for juveniles and the required measures for adults, the standards that must be satisfied for land use and permitting decisions on Project lands, and the requirement to mitigate for any past incidental take that was not sufficiently mitigated in the event the incidental take permit is terminated early provides each Plan Species with the maximum protection practicable and minimizes and mitigates the impacts of any taking as is required by Section 10 of the Endangered Species Act. Furthermore, in order to make sure that everything is being done to protect, restore and increase the abundance of the Plan Species and their habitat, the Agreements mitigate for all the unavoidable mortality associated with the Projects through the Tributary Conservation Plan and the Hatchery Compensation Plan. Therefore, the 100% No Net Impact standard of the Agreements is truly revolutionary in salmonid management on the Columbia River.

How are the standards measured?

Survival Standards. Measurement and evaluation of the 95% Juvenile Dam Passage Survival will commence by the 2003 juvenile migration unless agreed to otherwise by the coordinating committee. However, the 2003 date was established under the assumption that the regulatory review process for the Agreement would take no more than 18 months from the date the Agreements were filed with NMFS in 1998. Due to the fact that regulatory review process has taken longer than anyone ever expected, it may be necessary to revisit the 2003 date.

[36] Rocky Reach at Section V.1.; Rock Island at Section V.1.
[37] Rocky Reach at Section V.2.; Rock Island at Section V.2.
[38] Rocky Reach at Section X.6.; Rock Island at Section X.6.

The completion of measurement and evaluation is expected to take three years.[39] The 91% Project Survival measurement may also occur by 2003 juvenile migration should the coordinating committee elect.[40] The intent of the language addressing "95% Juvenile Dam Passage Survival and 91% Project Survival"[41] is to expressly allow the coordinating committee to measure juvenile survival through the reservoir, forebay, dam, and tailrace as opposed to just measuring juvenile survival through the forebay, dam, and tailrace. The parties wanted to allow this option because it is easier to measure survival through the reservoir, forebay, dam and tailrace, than just through the forebay, dam, and tailrace. The parties intended to require only the measurement of 95% Juvenile Dam Passage Survival by the 2003 juvenile migration.

The parties did not intend to require the measurement of 91% Project Survival on any certain date. The reason is that technology does not currently exist to measure the adult component of 91% Project Survival. This is explained in greater detail above in the section "What is the biological plan? (the standards), *The Survival Standards*."

The Agreements do not contain the protocol to be used to measure 95% Juvenile Dam Passage survival because in 1998, when the Agreements were developed, the parties thought that the regulatory approval process would be completed within 18 months of filing. The parties felt that this level of detail was not necessary for the Agreements and would simply slow down the implementation process. Therefore, the parties established a process to create the protocol, with general parameters for the protocol.[42] The Agreements required the coordinating committee to develop the protocol by March 1, 2001. This provided a grace period of two years before the protocol would be needed to work out any disagreements. Since March 1, 2001 has arrived before regulatory review process for the Agreements has been completed the parties need to revise this date.

Tributary Conservation Plan. The purpose of the Tributary Plan is to create and fund projects for the restoration and protection of Plan Species habitat. This will provide 2% compensation for the Unavoidable Project Mortality. The Tributary Plan, however, does not require the Parties to actually measure whether the Tributary Plan compensates for exactly two percent Unavoidable Project Mortality.[43] The parties that developed the Agreements made this decision based upon the fact that it was unlikely that measurement could occur, and that if it could occur, the cost and time associated with measurement would outweigh any benefit it could possibly produce. However, the individual tributary projects and budgets that make up the Tributary Plan will be evaluated by the Tributary

[39] Rocky Reach at Section IV.3.b.; Rock Island at Section IV.3.b.
[40] Rocky Reach at Section IV.3.b.; Rock Island at Section IV.3.b.
[41] Rocky Reach at Section IV.3.b.; Rock Island at Section IV.3.b.
[42] Rocky Reach at Section IV.3.c.; Rock Island at Section IV.3.c.
[43] Rocky Reach at Section VII.2.; Rock Island at Section VII.2.

Committee.[44] The Tributary Committee will select projects that work toward furthering the purpose of the Tributary Plan for Plan Species.[45]

Hatchery Compensation Plan. The Hatchery Compensation Plan will provide 7% compensation for the Unavoidable Project Mortality. Measurement and evaluation of the Hatchery Program is explained above in the section "What is the biological plan? (the standards), *Hatchery Compensation Plan.*"

Unavoidable Project Mortality. The measurement and evaluation of Unavoidable Project Mortality is explained above in the Section ""What is the biological plan? (the standards), *Unavoidable Project Mortality.*"

What happens if juvenile survival results fall short of expectations?

Measurement and evaluation of 95% Juvenile Dam Passage Survival or the juvenile component of 91% Project Survival at the end of Phase I will begin by the 2003 juvenile migration unless this date is revised. The process is expected to take three years. Thus, there is a three year window where the parties do not know whether or not the survival standard has been achieved. In order to insure the protection of the Plan Species the Agreements contain a process which can be used to provide an interim evaluation of the Projects' survival and, as necessary, require the implementation of additional interim measures.[46]

If measurement and evaluation of 95% Juvenile Dam Passage Survival or the juvenile component of 91% Project Survival at the end of Phase I of the Juvenile Passage Survival Plan has not been achieved, then the coordinating committee will decide on additional "tools"[47] to implement to achieve the survival standard. The District will implement the tools selected by the coordinating committee before the next migration period. These tools, which could include Trading[48] and additional spill, will be selected by the coordinating committee based on technical feasibility, availability, and adherence

[44] Rocky Reach at Section VII.3.a.; Rock Island at Section VII.3.a.
[45] Rocky Reach at Section VII.4.c.; Rock Island at Section VII.4.c.
[46] Rocky Reach at Section IV.3.a.iii.; Rock Island at Section IV.3.a.iii.
[47] The term "tools" is a defined term in the Agreements to mean "any action, structure, facility or program (on-site only) at the Project, except those prohibited in Section IX.10 'Drawdowns/Dam Removal/Non-Power Operations' that are intended to improve the survival of Plan Species migrating through the Project. Tools do not include fish transportation unless otherwise agreed by the Coordinating Committee. This term is a sub-set of Measures". Rocky Reach at Section XII.17; Rock Island at Section XII.17.
[48] The term "trading" is a defined term in the Agreements to mean "the allocation of the net survival benefits in excess of 95% Juvenile Dam Passage Survival and 91% Project Survival from a downstream Dam or Project to an upstream Dam or Project, or on a stock specific basis, from an upstream Dam or Project to a downstream Dam or Project in lieu of offsite compensation measures for the affected stocks." Rocky Reach at Section XII.18; Rock Island at Section XII.18.

to the total dissolved gas requirements.[49] The coordinating committee must jointly decide which additional tools will allow the District to achieve 95% Juvenile Dam Passage Survival or 91% Project Survival. The following criteria will be used: likelihood of biological success; time required to implement; and cost-effectiveness of solutions. The balancing of a tool's cost-effectiveness will only take place where two or more alternatives are comparable in their biological effectiveness.[50]

A cycle of implementation of additional tools and measurement is repeated until the survival standards are achieved.[51] If a solution cannot be identified to achieve the standards, then any Party may take action to withdraw from the Agreements on the basis that it is impossible to achieve the standards in the Agreements, or take action under any other provision of the Agreements.[52]

How do disagreements get resolved?

Rule. A central feature of the Agreements is the process for resolving disputes. All disputes under the Agreements are resolved according to the Agreements' dispute resolution process. This includes those disputes involving the Passage Survival Plan, the Hatchery Plan, the Tributary Plan, and compliance with the NNI standard and its component survival standards for the Dam, Project, and Unavoidable Project Morality.[53]

Exceptions. There are three circumstances were disputes are not required to be resolved through the Agreements' dispute resolution process. NMFS has reserved the right to use its enforcement powers and remedies of the ESA without first resorting to the Agreements' dispute resolution process. [54] While NMFS intends to utilize the Agreements' dispute resolution process and has the authority to agree to alternative dispute resolution, NMFS' reserved this right to insure that it was not delegating away its authority.

In addition, neither the Agreement nor the dispute resolution process can be used to abridge, limit, diminish, abrogate, adjudicate, or resolve any Indian right reserved or protected in a treaty, executive order, statute or court decree.[55]

Lastly, any Party can require the matter to be decided at FERC or in a court of competent jurisdiction. However, disputes must proceed through Stage 1 and 2 of the

[49] Rocky Reach at Section IV.6.; Rock Island at Section IV.6.
[50] Rocky Reach at Section IV.7.a-c.; Rock Island at Section IV.7.a-c.
[51] Rocky Reach at Section IV.3.10.; Rock Island at Section IV.3.10.
[52] Rocky Reach at Section III.3.; Rock Island at Section III.3.
[53] Rocky Reach at Section XI.1.a.; Rock Island at Section XI.1.a.
[54] Rocky Reach at Section XI.1.b.; Rock Island at Section XI.1.b.
[55] Rocky Reach at Section XI.1.c.; Rock Island at Section XI.1.c.

dispute resolution process before a Party invokes the jurisdiction of FERC or a court.[56] The Agreement, however, is not intended to create jurisdiction in any court.[57]

Dispute Resolution Process:

Stage 1: Coordinating Committee

Any matter, which involves compliance with the Agreement, is first referred to the respective committee dealing with that issue. That committee has twenty days to resolve the dispute. If there is no resolution within twenty days the matter may proceed to the next stage in the dispute resolution proceeding.[58]

Stage 2: Policy Committee

Any Party may refer the dispute to the Policy Committee, who shall have thirty days to convene and consider the dispute. If there is no resolution at the end of thirty days any Party may either proceed to the next stage or invoke FERC jurisdiction.[59] If a Party decides to invoke the FERC process or proceed to a court of competent jurisdiction then the dispute resolution procedure is terminated.[60] Provided a Party wishes to continue the dispute resolution proceeding, a party may seek to have the issue mediated by the Third Stage.

Expedited Process. If an issue must be resolved within 30 days, and does not involve a total estimated cost of $325,000 in 1998 dollars, then an expedited procedure is used. All Parties are given notice that the coordinating committee will have the matter finally resolved at an identified coordinating committee meeting.[61] If the coordinating committee does not reach a consensus, then any Party may refer the matter to dispute resolution under Stage 3 by giving notice.[62] The mediator has 15 days from the date selected to hear and resolve the dispute.[63] While the mediation decision is not binding, it may be admitted as evidence in any action to resolve the dispute.[64] The mediator's decision, however, must be implemented immediately.[65]

[56] Rocky Reach at Section XI.3.c.; Rock Island at Section XI.3.c.
[57] Rocky Reach at Section XI.1.d.; Rock Island at Section XI.1.d.

[63] Rocky Reach at Section XI.7.d.; Rock Island at Section XI.7.d.
[64] Rocky Reach at Section XI.7.d.; Rock Island at Section XI.7.d.
[65] Rocky Reach at Section XI.7.e.; Rock Island at Section XI.7.e.

Standard Mediation Timing. Under the standard mediation procedure, the Parties shall agree on a mediator within 10 days of the date mediation was first requested.[66] The mediator shall have control over the process of mediation, however, it must be completed within 30 days of the date the mediator is selected.[67] If the Parties do not come to an agreement, then the mediator may prepare, within 45 days, an opinion on how the decision should be resolved.[68]

Expedited Dispute Resolution Timing. The expedited procedure can result in the issuance of a mediation decision sixteen days from a coordinating committee impasse.[69] This assumes that the Chief Judge can be contacted in one day, and the Chief Judge appoints the mediator that day. According to the expedited procedure, if the Parties are unable to agree on a single mediator within ten days of the mediation request, then the Chief Judge of the United States District Court for the Eastern District of Washington shall appoint the mediator.[70]

Dispute Resolution Twists. If the Parties do not select a mediator within ten days of the date that mediation is requested, the Chief Judge of the U.S. District Court for the Eastern District of Washington appoints the mediator.[71] While mediation is non-binding, the mediator will issue a decision. This decision can be introduced as evidence at FERC or Court.[72] The purpose of the mediation decision is to create a dynamic where the parties will stop fighting. The Parties have found after working together for many years that there are times when they just want to argue the merits of their position to a neutral third party and have a decision rendered. Once the decision is rendered it will not likely be appealed. As an incentive not to appeal, and to make sure that the dispute resolution process was not a waste of time, the Parties agree that they will allow the mediation decision to be entered into evidence upon appeal. The Parties intentionally did not decide the weight that should be given to the decision. This way each side could argue for or against the opinion without knowledge of the weight FERC will give to the decision. This dynamic coupled with the fact that the Party bringing the issue to dispute resolution must prove their case by a preponderance of the evidence should prevent most appeals.[73]

What is the term of the Agreements?

[66] Rocky Reach at Section XI.3.d.i.(1).; Rock Island at Section XI.3.d.i.(1).
[67] Rocky Reach at Section XI.3.d.i.(4).; Rock Island at Section XI.3.d.i.(4).
[68] Rocky Reach at Section XI.3.d.ii.; Rock Island at Section XI.3.d.ii.
[69] Rocky Reach at Section XI.7.d.; Rock Island at Section XI.7.d.
[70] Rocky Reach at Section XI.3.d.2.; Rock Island at Section XI.3.d.2.
[71] Rocky Reach at Section XI.3.d.2.; Rock Island at Section XI.3.d.2.
[72] Rocky Reach at Section XI.7.; Rock Island at Section XI.7.
[73] Rocky Reach at Section XI.1.e.; Rock Island at Section XI.1.e.

The Agreements will remain in effect 50 years from the date the Agreements are executed by all Parties and regulatory approvals are received.[74]

How do people get out of the Agreements?

Triggers

There are several ways the Agreements will terminate automatically. The first way is at the end of the fifty-year term of the Agreements, as seen in Section I. The second way is if the FERC issues the District a non-power license for the Project. The third option is in the event the FERC orders removal of the Project. The fourth reason is if FERC orders drawdown of the Project. If the District's FERC license is terminated or transferred to another entity than the District's obligations under these Agreements are terminated. The Parties agree, however, that the terms of these Agreements are binding on their respective successors and assigns.[75]

A party may withdraw from the Agreements when fifteen years have elapsed from March 1, 1998 provided that NNI has not been achieved and maintained, or the Project has achieved and maintained NNI but the Plan Species are not rebuilding and the Project is a significant factor in the failure to rebuild.[76] The reason for this provision is that the Juvenile Passage Plan requires a cycle of implementing and testing measures to achieve 95% Juvenile Dam Passage Survival. As long as the District implements the measures required by the coordinating committee it is not in violation of the Agreements if 95% Juvenile Dam Passage Survival is not achieved. Since this process could go on throughout the term of the Agreements, an opportunity was provided to allow a Party to withdraw; hence the section is titled "Enough Already". Since the only restrictions on the measures the coordinating committee can recommend are drawdown, non-power operations, or dam removal, theoretically the only reason to withdraw would be to advocate for the implementation of one of these measures. But, a Party will hopefully feel that the Agreements provide the best process possible for managing salmon issues at the Projects, and not choose to withdraw from the Agreements.

This "Enough Already" provision applies to NMFS and USFWS differently than any other Party to the Agreements. NMFS or USFWS may not elect to withdraw unless they intend to explicitly seek drawdown, dam removal, or non-power operations. But, under these circumstances NMFS and the District may agree to allow NMFS to pursue

[74] Rocky Reach at Section I.; Rock Island at Section I.
[75] Rocky Reach at Section II.1.; Rock Island at Section II.1.
[76] Rocky Reach at Section II.2.a.i.; Rock Island at Section II.2.a.i.

drawdown, dam removal, or non-power operations and keep NMFS in the Agreements and keep NMFS from terminating the incidental take permit.[77]

A Party to the Agreements, other than the District, may withdraw at any time based on non-compliance of the District to the provisions of the Agreements. The District cannot use its own failure to comply with the Agreements as a basis for withdrawal. However, out of fairness the District may withdraw from the Agreements if another Party to the Agreements is failing to comply with the Agreements.[78]

A Party may withdraw from these Agreements if a regulatory entity takes action that is detrimental to the achievement of the obligations each Party is given by these Agreements, and the regulatory entity's actions materially alter or are contrary to the terms of these Agreements.[79] For example, if NMFS revokes the incidental take permit required to implement the Agreements, then a Party may withdraw from the Agreements.[80]

In the event that all Parties agree in writing that the obligations imposed by these Agreements are impossible to achieve, then a Party may withdraw from the Agreements.[81]

Because a Party may withdraw from the Agreements, the Parties created a process to try to resolve their issue so that they would not withdraw. In the event a Party decides to withdraw from the Agreements, it shall provide all other Parties with notice, unless it is withdrawing due to non-compliance. After receipt of a notice to withdraw, the other Parties shall have 120 days from the date of the notice to provide notice of their intention to withdraw or the right to withdraw will be deemed waived. The notices are required to be in writing and either served in person or provided by U.S. Mail with a return receipt requested.[82] The Party seeking to withdraw must make itself available for at least one policy meeting where other Parties may attempt to persuade the Party not to withdraw. The policy meeting will take place within the sixty days after notice is given or the right is waived.[83]

In the event a Party does withdraw from the Agreements, there are no further restraints placed upon the withdrawing Party. Thereafter the withdrawing Party is not bound by the Agreements, and all rights and remedies of a non-Party are available to the

[77] Rocky Reach at Section II.2.a.ii.; Rock Island at Section II.2.a.ii.
[78] Rocky Reach at Section II.2.b.; Rock Island at Section II.2.b.
[79] Rocky Reach at Section II.2.c.; Rock Island at Section II.2.c.
[80] Rocky Reach at Section II.2.e.; Rock Island at Section II.2.e.
[81] Rocky Reach at Section II.2.d.; Rock Island at Section II.2.d.
[82] Rocky Reach at Section II.f.; Rock Island at Section II.f.
[83] Rocky Reach at Section II.3.; Rock Island at Section II.3.

withdrawing Party. The rights of a withdrawing Party is modified as set forth in Section II.5, Section IX.3.a and c, and Section X.5.[84]

In the event the Agreements are terminated, voided, or determined to be unenforceable then the District shall continue to implement the last measures agreed upon until FERC orders them to behave differently. The Parties, however, are not restrained from advocating to FERC measures to replace the Agreements. The exceptions to this rule are set forth in Section VII.4.f, Sections IX.3.a and c, Section X.5 and Section X.6.[85]

Specific Comments

1. Page S-15, 2-32, Alternative 3 (Applicants' Proposed Action – Project HCPs), 2nd paragraph. The text states that "the EIS required for implementing measures in the HCPs ..." An EIS may not be needed in order to implement measures in the HCPs. In most cased an environmental checklist or an environmental assessment will be sufficient.

2. Page S-15, 2-32, Alternative 3 (Applicants' Proposed Action – Project HCPs), 2nd paragraph. The text states that "implementing measures in the HCP would be undertaking by FERC with a separate Section 7 consultation with NMFS". It is the District's understanding that the HCPs will be presented to FERC with a request that they be incorporated into the project licenses. FERC's action many not require a new Section 7 consultation with NMFS and USFWS.

3. Page S-18, 2-35, last sentence before the start of Section S.5.3.6 and Section 2.3.3.6. The sentence reads "...to achieve 95 percent juvenile dam passage survival and 91 percent project survival." Replace the "and" between "juvenile dam passage" and "project survival rates" with an "or". While the word "and" is used in the HCPs, its use was an error. An errata sheet will be prepared for the final HCP on this issue. The intent of the parties was to require the measurement of 95% juvenile dam passage survival starting in 2003 as a default. However, the parties desired to leave the coordinating committee the discretion to forgo measurement of 95% juvenile dam passage survival and just measure the juvenile component of 91% project survival in 2003. There is not an obligation to measure 91% project survival in 2003. The coordinating committee will measure 91% project survival when an protocol can be developed.

4. Page S-23, 2.3.3.11, Project Cumulative Effects. This text attempts to summarize Section V "Reservoir As Habitat" of the HCPs. However, the summary omits an

[84] Rocky Reach at Section II.4.; Rock Island at Section II.4.
[85] Rocky Reach at Section II.5.; Rock Island at Section II.5.

important concept. The District agrees to consider cumulative impacts as part of its land use decision making.

5. Page S-24, 2-41, "Term of the HCPs", first paragraph, first sentence. The text states that "the 50-year term of the HCPs would not begin until the incidental take permits are issued." While correct, this sentence is a bit misleading. The 50 year term of the HCPs starts when the "Agreement is executed by all Parties and regulatory approvals are received..." HCP, Section I "Term of Agreement". Issuance of the requested incidental take permit from NMFS is only one of the regulatory approvals that must be received in order for the HCPs to become effective.

6. Page S-24, 2-41, "Transition Period" mischaracterize the current HCP activities. The PUDs are not conditionally implementing the HCPs. The PUDs have volunteered to perform activities that are consistent with the HCPs as a sign of good faith. The District is also implementing measures because even though the HCP is not in effect the 2003 deadline is approaching.

7. Page S-24, 2-41, "Transition Period" mischaracterize the interim protection plans. In 1997, with the full support of the NMFS and the USFWS, the PUDs voluntarily filed interim protection plans with the Federal Energy Regulatory Commission. The interim protection plans identified various portions of the HCPs that the District, NMFS and USFWS felt were worthwhile to implement in advance of completing the HCP negotiations. Measures were picked to assist the migration of newly listed Upper Columbia River steelhead. The interim protection plans proposed only a two year plan because the HCPs were expected to be in place within two years. The interim protection plans were informally expanded to include Upper Columbia spring chinook upon their listing. The PUDs requested that FERC approve the measures contained in the interim protection plans. FERC initiated consultation with NMFS over this proposed action. The consultation has yet to be completed, and FERC has yet to take action on the plans. Due to the time taken to complete this consultations, the interim protection plans have expired.

8. Page S-26, 2-43, "Compensation for Unavoidable Project Mortality", first two sentences. The meaning of the first two sentences is not clear. The District has not modified any portion of the incidental take permit applications that were filed with NMFS.

9. Page S-26, 2-43, "Hatchery Compensation Plan Issue" and Page 1-12 Section 1.5.2.6 "Federal Trust Responsibilities to Indian Tribes" overstates the issue in dispute. The HCP requires that 7 percent of the "unavoidable project mortality" associated with each project be mitigated through hatchery supplementation. HCP Section III.1. The HCP goes on to define the initial hatchery production commitment. HCP Sections

VIII.3. and 4. NMFS is in a position to evaluate the effects of the initial hatchery production commitment. However, hatchery production will vary over time depending upon the size of the runs. NMFS has been unwilling to opine that the hatchery program will always satisfy the Endangered Species Act. Since NMFS has been unwilling to define the hatchery levels that will satisfy the Endangered Species Act it is not possible to predict how the hatcheries will be utilized during the term of the HCPs. Hatchery production is a key incentive for the tribes' participation in and support of the HCPs as a comprehensive settlement. Without knowing how the hatcheries will be utilized during the term of the HCPs the tribes cannot effectively evaluate the benefits of the HCPs. As a result of this uncertainty the tribes are not supporting the HCPs.

10. Page S-29, 2-50, "Endangered Species Act Compliance." It is unknown whether the Project's current licenses comply with the Endangered Species Act since they were issued prior to the adoption of the Endangered Species Act. Also, assuming the Project licenses do not comply with the Endangered Species Act, under Alternative 1 the District could obtain incidental take permits addressing only listed species.

11. Page S-30, 2-51, "Future Provisions for Other Aquatic Species". The table should acknowledge for all three alternatives that the District could submit incidental take permits under Section 10 of the Endangered Species Act as a means of addressing the Endangered Species Act.

12. Page S-31, 2-52, "Dispute Resolution." The table incorrectly includes "binding arbitration" as a means for resolving disputes. The text on Page S.17 paragraph 2 does a better job of explaining the HCP's dispute resolution process; but, does omit two of the exceptions to utilizing dispute resolution. See discussion above under "The Agreements" for more thorough overview of the HCP's dispute resolution process.

13. Page S-33, 2-53, Section S.7.2.3 "Alternative 3", first full paragraph, second sentence. The text reads that in part "there is no requirement to provide the benefit of the doubt to the species of concern with respect to gaps in the information base and NMFS has no authority to determine what constitutes the best available information to be utilized in support of any decisions." This sentence infers that the HCP dispute resolution process may not comply with law. Such an inference is not correct. In the HCP, NMFS has expressly reserved its authority to monitor, modify, suspend, revoke and re-instate, and enforce its incidental take permit outside the HCP dispute resolution process. HCP Section X.3-5, and Section XI.1.b. Furthermore, the dispute resolution process will not produce a result that is binding upon NMFS unless NMFS agrees. HCP Section XI.5.c. The dispute resolution process is mediation with a twist. The twist is that the mediator will issue a decision that can be entered into evidence in a later proceeding. HCP Section XI. 5.c. The reason for the decision is to facilitate

settlement. No one knows what, if any, weight will be afforded the decision. Also, the parties' intent is that once the decision is rendered parties will not feel the need to proceed further. NMFS like any other agency has the authority to enter into dispute resolution processes. 5 USC Section 572(a), and 575(a)(1). Since a party may pursue any remedy available after exhausting dispute resolution it is in full compliance with the law. HCP Section XI. 3.c.

14. Page S-35, 1-31, Section S.8 "Decision to be Made", second to last paragraph, first sentence. The text states that "NMFS will prepare a biological opinion to determine if the implementation of the HCPs is likely to jeopardize the continued existence of listed species that are likely to occur in the Plan area. ..." The text goes on to discuss issues NMFS will analyze in the biological opinion, and explains actions NMFS may take based upon the results of the biological opinion. The process NMFS describes in the DEIS for evaluating the incidental take permit applications filed by the District are not consistent with Section 10 of the Endangered Species Act. Section 10(a)(2) of the Endangered Species Act defines the process NMFS must follow to evaluate an incidental take permit application. 16 U.S.C. Section 1539(a)(2). This process does not require NMFS to consult with itself under Section 7 of the Endangered Species Act. Section 10 defines the complete process NMFS must follow to evaluate an incidental take permit application.

15. Page S-35, 1-31, Section S.8 "Decision to be Made", second to last paragraph, first sentence. The text states that "if the NMFS' biological opinion finds that the proposed actions are not likely to jeopardize the continued existence of the listed species ..., the permits can be approved." While true, NMFS must also make the findings required by Section 10 of the Endangered Species Act in order to issue the requested incidental take permits.

16. Page S-41, 2-61, "Land Use, Project Area, Alternative 3". The text does not correctly reflect the HCPs. In the HCPs the PUDs will consider cumulative effects of land use decisions, provide the signatories to the HCPs with opportunity to provide comments on permitting decisions, and notify permit applicants that their proposed use or occupancy of may result in incidental take of listed species and require authorization of NMFS or USFWS. HCP Section V "Reservoir as Habitat".

17. Page S-42, 2-63, "Economics, Project Area."; also, Page 4-61 Section 4.7 "Socioeconomic". Why is there no analysis of how spill and the other measures in each alternatives reduce the generating capacity and energy generated from the projects? This is a very significant effect of all the alternatives given the energy emergencies facing the Western United States, the Northwest, and Chelan County. Reduced generating capacity and reduced energy output have a direct effect on the ability of the projects to meet peak load demands for the District's own loads, and to

prevent or minimize energy emergencies in the Northwest and Western United States. The failure of the projects to meet peak load demands for the District's own loads exposes the District's loads to the extreme costs of energy in the Northwest and the West, and also to the risk that energy will not be available at any price. These issues vary dramatically between the three alternatives reviewed in the DEIS.

18. Page 1-1, Key Terms, "No Surprises Policy". The District understands that the term "no surprises policy" refers to the rules set forth in 50 CFR Section 222.303(g).

19. Page 1-4, Section 1.5, "Regulatory Framework", third sentence. What does "other Federal laws and regulations" mean?

20. Page 1-9, continuation of Section 1.5.2.4, "FERC Regulatory Requirements", 3rd full paragraph, second sentence. Text reads "These measures will supercede any settlement agreements pertaining to Plan." Insert "Species" after "Plan."

21. Page 1-10, Northwest Power Act, 1st paragraph, second sentence. The text reads "The Mid-Columbia utilities are subject to the Act ....". The term "Mid-Columbia utilities" is not defined in the DEIS. This DEIS relates to the projects operated by Chelan and Douglas PUDs. Also, Chelan and Douglas PUDs are not subject to the Northwest Power Act. FERC considers the plans developed pursuant to the Northwest Power Act when licensing the projects.

22. Page 1-11, "Title 77 Revised Code of Washington"., First sentence. The sentence addresses "wildlife". This reference is not correct for the purposes of the proposed agreements being reviewed in the DEIS. Relevant for these purposes is the State's responsibility to "preserve, protect, and perpetuate wildlife, fish, and wildlife and fish habitat." RCW 77.04.055(1).

23. Page 1-13, Section 1.6.1 "Alternative 1 (No Action), 2nd paragraph, 2nd sentence. The text states "...the years to address engineering, bond, and resource related issues...". The inclusion of the term "bond" is not correct in this sentence. The project licenses have not been amended to address the issuing of bonds.

24. Page 1-16, 3rd paragraph, last sentence. Text reads "This allows the HCPs to be updated with information received during the comment period...". This sentence incorrectly explains the NEPA process. Comments received by NMFS on the DEIS will be considered by NMFS when preparing the FEIS. The HCPs are multiparty, negotiated settlement agreements. The fact that NMFS receives a comment on the DEIS does not mean that the HCPs will be modified.

25. Page 1-17, Section 1.7 "Background", 4th paragraph. The region faces economic hardship in 2001 as power shortfalls hit the region. The current January-through-July runoff forecast has the region's water supply at 55 percent of normal, assuming normal precipitation for the March-through-July period. If this year's water conditions match 1977's, the lowest on record, the council predicted 2001 shortfalls could approach 8000 MW-months, with the deficit in May reaching 3300 MW-months. If the conditions match 1944 conditions, a year with just slightly higher runoff than the current projection, the total energy deficit across the months of April through August is 5,600 MW-months, with the deficit in May reaching 2,700 MW-months. (The Northwest Power Planning Council, "Northwest Electricity Markets in 2001: Status and Proposed Actions", March 26, 2001). The report states "it is a virtual certainty that emergency operations will be necessary during spring and summer to keep the electricity system from suffering outages." (NWPPC, 2001)

26. Page 1-18, continuation of Section 1.7 "Background", 1st full paragraph, 1st sentence. Also, Page 6.5, definition of "Mid-Columbia River." On Page 1-18, the text defines the Mid-Columbia River as "the area of the river between the Chief Joseph project and the confluence of the Yakima River." On Page 6.5, the text defines the Mid-Columbia River as "portion of the Columbia River that begins at its confluence with the Snake River up to the Chief Joseph dam." These two definitions are not consistent. The term "Mid-Columbia River" is not used in the HCPs. However, the HCP's Tributary Plan's, Plan Species Account can be spent only on projects "within the Columbia River watershed (from the Chief Joseph tailrace to the Rock Island tailrace), and the Okanogan, Methow, Entiat and Wenatchee River watersheds...". HCP Section VII.2.

27. Page 1-14, Section 1.7.2.2 "National Marine Fisheries Service", 1st paragraph, 1st sentence. The text reads "Many of NMFS' past studies, listings, and rules are directly relevant to the Mid-Columbia hydroelectric projects. ...". The term "directly" is not accurate. The documents discussed in this paragraph are "indirectly" relevant to Chelan and Douglas PUD's hydroelectric projects. They are not "directly" relevant to Chelan and Douglas PUD's hydroelectric projects because they do not relate to these projects. They relate to the Federal hydroelectric projects on the Columbia River.

28. Page 1-29, Section 1.7.3.1 "Mid-Columbia PUD FERC Agreements", 3rd sentence. This sentence refers to the Rock Island Settlement Agreement. The tribes listed in the text are not the only signatories to this agreement. The parties to the Wells Settlement Agreement, while similar to those of the Rock Island Settlement Agreement, are not the same.

29. Page 1-29, Section 1.7.3.2 "Major Bond and Sales Agreements for the Projects". This text is grossly incorrect. As of March 14, 2001, the District's total estimated bonds

outstanding is $886,076,000.[86] This indebtedness is secured by the revenue generated by the District's consolidated hydro system.

30. Page 1-33, continuation of Section 1.10 "Background Summary", 1st full paragraph, 2nd to last and last sentences. The text reads "Under the agreement, the utilities would have the ultimate authority in the decision making process, as long as the no net impact standards are being met. If all parties agree that the standards have not been achieved, the coordinating committees would have an increased role in the decision making process" These sentences do not correctly summarize the HCPs. For example: the District has the "ultimate decision on pursuit and implementation of Tools during Phase I" of the Juvenile Dam Passage Survival Plan. HCP Section IV.2.a.i. In Phase II of the Juvenile Dam Passage Survival Plan the coordinating committee has the decision making authority. HCP Section IV.a.6 – 8. In Phase III of the Juvenile Dam Passage Survival Plan the coordinating committee has the decision making authority related to continued measurement and evaluation. HCP Section VI.a.11. In the Adult Passage Plan, the agreement lays out the actions to be taken. HCP Section VI.b. With regard to the Hatchery Compensation Plan and the Tributary Compensation Plan the "JFP accepts the responsibility to develop plans and programs necessary to implement the Tributary Conservation Plan and the Hatchery Compensation Plan. HCP Section III.4.

31. Page 2-2, Section 2.1 "Development of Alternatives". Throughout the development of the DEIS the District has and still expresses concern about the choice of alternatives in the DEIS. The DEIS has not chosen as alternatives measures or mixes of measures that seek to mitigate the effects of the projects on salmon and steelhead. NMFS chose as alternatives competing legal process for establishing the measures to mitigate the effects of the projects on salmon and steelhead. This is a very unusual, and questionable method for evaluating the environmental effects of the proposed HCPs. The DEIS should be amended to provide more traditional alternatives. Alternatively, the rational and legal authority for this decision is not clearly explained in the DEIS, and should be incorporated into the FEIS.

32. Page 2-2, Section 2.1 "Development of Alternatives", 5th paragraph, 4th sentence. Text reads "to be in compliance with the take prohibitions of Section 9, FERC would implement the measures ...." FERC would be in compliance with Section 9 of the ESA by implementing the provisions contained in NMFS biological opinion and incidental take statement. However, FERC is not obligated to do so. FERC may take other action as long as it is not likely to jeopardize the continued existence of any

[86] Official Statement, Public Utility District No. 1 of Chelan County, Washington $143,995,000 Chelan Hydro Consolidated System Revenue Bonds consisting of $65,620,000 Series 2001A and $78,375,000 Series 2001B, page iv (March 1, 2001)

endangered species or threatened species or result in the destruction or adverse modification of habitat of such species which is ... critical...". 16 U.S.C. Section 1536(a)(2); Aluminum Company v. BPA, 175 F.3d 1156, 4394-4395 (9th Cir. 5/10/99).

33. Page 2-7 Section 2.2.1.2 "Rocky Reach Dam", first paragraph, last three sentences. The text describing the rehabilitation work at Rocky Reach is outdated. The following edits are recommended so that the text is current:

"...Unites 1 through 7 are currently vertical shaft Kaplan turbines installed during the original construction in 1962, while fixed-blade propeller units were installed in Unties 8 through 11 in 1971. ~~One~~ Two of these fixed-blade propeller units ~~has~~ have been rehabilitated and replaced with ~~a~~ Kaplan turbines~~ unit,~~. A third unit is currently undergoing rehabilitation and the ~~other three~~ remaining units ~~are~~is scheduled to be ~~replaced~~ rehabilitated by June ~~2003~~2002. In addition, all but one of the original Kaplan units have been rehabilitated and replaced with more efficient Kaplan turbines~~, which~~. This turbine work is ~~are~~ expected to increase juvenile fish passage survival."

34. Page 2-11, Table 2-4, and all text that incorporates or explains information conveyed in the table which includes but is not limited to the text in Section 3.2.6.4 and Table 3-3. The juvenile dam passage information included in the table does not take into account project specific information, and when project specific information is reviewed it is dismissed in favor of information developed from other hydroelectric projects without explanation. Set forth in Attachment A is the most project-specific survival information available for both the Rocky Reach and Rock Island Projects. This information is primarily based on information collected at these Projects through the various studies identified in the references. Copies of the studies are available upon request.

35. Page 2-12, 1st paragraph, last sentence. The text reads "the information also indicates that survival is higher through the spillway and bypass system than through the turbine units." What is the citation for this statement? The statement does not logically flow from the materials cited in the paragraph.

36. Page 2-14, Rocky Reach Dam, 3rd sentence. The text reads "Passage efficiency tests ... and 52 percent of the PIT-tagged steelhead...". "PIT-tagged" is not correct. These were "radio tagged" steelhead.

37. Page 2-14, Rocky Reach Dam, 5th sentence. The text reads "In 1999, guidance ... 32 percent of the chinook and 53 percent of the steelhead passed ...". In both cases, these were radio tagged fish.

38. Page 2-15, Rocky Reach Dam, 2nd paragraph, 1st sentence. Text reads "Studies at the dam have shown that between 8 and 18 percent ..." This text is not consistent with the text on page 4-18 which uses 19 percent and not 18 percent. Nineteen percent is the correct number.

39. Page 2-16, Rock Island Dam, 3rd paragraph, 3rd sentence. The text reads "the spill passage rates for other species were estimated at 20, 33, and 35 percent for sockeye, fall chinook and coho salmon in 1998." What is the citation for this information?

40. Page 2-16, Rock Island Dam, 4th paragraph, 1st sentence. The text reads "A subsequent study indicated that survival rates through modified bay with deeper stilling basins may be near 100 percent ...." What is the citation for this information?

41. Page 2-16, Section 2.2.3.2 "Adult Passage", 1st paragraph, 5th sentence. The text reads "The delay and stress that adults experience during passage through multiple dams may reduce their spawning success." Please explain the scientific bases for this information, and provide a citation for the studies relied upon to make this statement.

42. Page 2-17, continuation of Section 2.2.3.2 "Adult Passage", 3rd paragraph, 1st sentence. The text reads "Survival rates of adult salmon and steelhead passing through the Mid-Columbia River have not been estimated due to insufficient radio-telemetry data." This is not correct. Currently, technology does not exist to measure adult survival. Therefore a technology limitation, not an insufficiency of radio-telemetry data, is the reason for no survival information.

43. Page 2-17, Section 2.2.3.3 "Adult Reservoir Passage", 1st paragraph, 4th sentence. The text reads "However, the reservoirs can increase the potential for wandering or straying (lost orientation), that could lead to higher pre-spawning mortality or reduced spawning success (Volkman 1995)." This conclusions are not contained in Volkman 1995 and cannot be inferred from the radio telemetry data contained in Volkman 1995. No evidence exists to support these statements.

44. Page 2-27, Section 2.2.3.3 "Adult Reservoir Passage", 1st paragraph, 5th sentence. The text reads "Higher water temperatures as a result of project reservoirs may also lead to higher prespawning mortality." What is the citation for this information?

45. Page 2-27, continuation of Section 2.3.2 "Alternative 2 (Section 7 Consultation)", 6th paragraph, 2nd sentence. The text reads "Evaluations conducted as part of the Quantitative Analytical Report (QAR) (NMFS 2000b) ..." The QAR is also discussed in detail in Section 4.2.1 "Quantitative Analytical Report". The QAR has not yet produced a final, peer reviewed document. Furthermore, the document cited at NMFS 2000b is a draft internal NMFS document. NMFS has yet to produce a copy of this

document after numerous requests. The District objects to NMFS citing QAR results anywhere in this document or in any other document (yet alone devoting 10 pages to it in Section 4.2.1, pages 4-6 through 4-16) until the QAR results are made public, finalized and peer reviewed. This comment relates to all references to the QAR in the DEIS. Without a copy of the QAR the District has no way to comment on portions of the DEIS related to the QAR. The District reserves the right to submit comments on the QAR until it receives a copy of the QAR and has had sufficient opportunity to review the QAR. Nevertheless, based upon the information provided in the DEIS and the District's limited knowledge of the QAR, the District objects strongly to NMFS' use of the QAR results. Most of the conclusions relied upon the DEIS are drawn from the portion of the database that dates back to only 1980 (p. 4-7) while the entire database dates back to the 1960s. This misrepresents the long term database. Conclusions based upon long term database shows dramatically different outcomes when compared to the conclusions based upon the short term database. While NMFS acknowledges the existence of data going back to the 1960s, it is dismissed as potentially too "optimistic" without a thorough explanation. (p. 5-11) The best scientific information available is the entire database which takes into consideration ocean cycles that were known to be more productive than the ocean conditions in the 1980's and 1990's. During the 50 year term of the proposed HCPs ocean conditions are likely to cycle back to more productive periods similar to the 1960s. This rational is supported by the current 2000 and 2001 improvement in runs that is attributed to greatly improved ocean conditions.

46. Page 2-35, continuation of Section 2.3.3.5 "HCP Performance Standards" 1st full paragraph. This paragraph was re-written from its mirror paragraph on page S-18. The text on page S-18 provides a clearer explanation.

47. Page 2-35, continuation of Section 2.3.3.5 "HCP Performance Standards" 2nd full paragraph, 2nd sentence. The text cites to the 1995 Federal Columbia River Power System biological opinion for the lower Snake and Columbia River projects (NMFS 1995). NMFS 1995 biological opinion has been superceded by its 2000 biological opinion. In 2000, USFWS also issued a biological opinion for bull trout. Therefore, this text should be updated to refer to the current biological opinions.

48. Page 2-35, continuation of Section 2.3.3.5 "HCP Performance Standards" 6th full paragraph, last sentence. The text reads "...to achieve 95 percent juvenile dam passage survival and 91 percent project survival." As explained in earlier comments, the coordinating committee will measure only 95% Juvenile Dam Passage survival. However, the coordinating committee may elect to measure the juvenile component of 91% Project Survival. If the results of the standard that was measured was not achieved, then the coordinating committee would identify the tool for the District to

implement by the next migration. It may be necessary to revise the HCP text to clarify this process.

49. Page 2-49 Section 2.6.1 "Alternative 1 (No-Action)". The text under this heading is introductory to all the alternatives, not specific to Alternative 1. See page S-28.

50. Page 3-27, Section 3.2.2.2 "Abundance". This section should be updated with 2000 fish counts and with projected fish counts for 2001. Fish counts showed a dramatic increase in 2000 and are projected to be even better in 2001. This information is very significant. Without this information the text is misleading.

51. Page 3-37, Rocky Reach, 3rd paragraph 2nd sentence. The text reads "the cumulative delay at nine dams on the Columbia River likely decreases spawning success." What is the citation for this information?

52. Page 3-39, Rocky Reach, 3rd paragraph, 1st sentence. The text reads "Based on juvenile radio-telemetry evaluations conducted in 1998, approximately 49 percent of the radio-tagged steelhead and 61% of the radio-tagged spring-run chinook salmon passed the project via the powerhouse (English et al. 1999)." This data is not correct. The correct citation should be English et al. 1998, not English et al. 1999. Also, 49 percent should be 34 percent, and 61% should be 51%.

53. Page 3-39, Rocky Reach, footnote 2. Footnote 2 reads "Radio-tagged fall chinook obtained from the East Bank Hatchery ... in 1997 and 1998 (e.g., approximately 81% powerhouse passage in ... via the powerhouse at significantly higher rates than the ..." The reference to 1997 is not correct and should be deleted. English et al. 1998 related to 1998 and 1997. Also, the use of the term "significantly" is not correct in this sentence. The term "significantly" has a meaning in statistics. The term infers that statistics were used to test a hypothesis. The statement made in the sentence is not the result of a statistical test. Therefore, use of the term "significantly" infers a level of credibility to the sentence that is not correct.

54. Page 3-40 continuation of Rocky Reach Dam, 1st paragraph, 1st sentence. The text reads "Lady et al. (2000) ... and English et al. (1999) estimated that 58 and 40 percent of the radio-tagged..." The estimates of 58 and 40 are not correct. They should be 50 and 30.

55. Page 3-40, continuation of Rocky Reach Dam, 2nd paragraph, last sentence. The text reads "Although neither evaluation was able to ... the pilot level survival evaluation conducted using radio-tagged steelhead in 1999 estimated direct and indirect survival at 89.7 percent (Lady et al. 2000), suggesting that the indirect effects associated with turbine passage are more significant than those seen at the bypass system or

spillway." The radio tag study cited in this sentence indicates a lower than desired direct and indirect survival at the project. NMFS should clearly explain why it is appropriate to use the results of a radio-tag study in this instance when the study shows low levels of survival, and not use the results of radio tag studies in other instances when the results of radio tag studies show high levels of survival. The District continues to object to NMFS's inconsistent use of study results, and failure to acknowledge the results of studies that show survival levels favorable to the District.

56. Page 3-43 Rocky Reach, 1st paragraph 2nd sentence. The text reads: "Passage efficiency tests conducted ... yearling chinook salmon and 51 percent of the PIT-tagged steelhead passed the project via this route (English et al. 1998a)." This sentence is not correct. 51 percent should be 52 percent, and PIT-tagged should be radio tagged.

57. Page 3-43 Rocky Reach, 1st paragraph 4th sentence. The text reads: "Passage efficiencies in 1999 ... 32 percent for chinook salmon, and 11 percent for sockeye salmon (Mosey et al. 2000)." This sentence is not correct. 11 percent should be 16 percent.

58. Page 3-43 Rocky Reach, 1st paragraph 5th sentence. The text reads "Radio telemetry evaluations in 1999 also indicated that about 57 percent of steelhead passed the project through the bypass." What is the citation for this information? The District is not aware of any study that produced this information.

59. Page 3-43 Rocky Reach, 1st paragraph, last sentence. The text reads "The combined spillway and bypass ... and between 62 and 64 percent for steelhead (Lady et al. 2000)." This information is not correct. 62 should be 72, and 64 should be 74.

60. Page 3-43 Rocky Reach, 2nd paragraph, 1st sentence. The text reads "In both 1997 and 1998...". This is not correct. The evaluation was done only in 1998. The evaluation was not done in 1997.

61. Page 3-43 Rocky Reach, 2nd paragraph, 2snd sentence. The text reads "In 1998, the bypass efficiency for naïve chinook salmon was substantially lower (19 percent) ... (English et al. 1998a)." This is not correct. 19 percent should be 22 percent.

62. Page 3-43, Rocky Reach, 5th paragraph, 3rd sentence. The text reads "The temporary bypass outfall site, located in front of the turbine unit four upwelling, ..." This is not correct. Unit four upwelling should be replaced with unit three upwelling.

63. Page 3-44, Section 3.2.6.4 "Total Project Survival – Juvenile Migrants". The discussion of project survival is not correct. The obligation is that "The District shall

also achieve and maintain 91% Project Survival ... which means that 91% of each Plan Species, juvenile and adult combined, survive Project effects, including delayed mortality wherever it may occur." HCP Section IV.1.a. The first sentence in this section of the DEIS fails to account for the fact that project survival includes "delayed mortality wherever it may occur." Also, the HCP does not define a protocol for measuring project survival as inferred from the DEIS. The HCP leaves it to the Coordinating Committee to establish the measurement protocols. HCP Section IV.3.c.

64. Page 3-47 Section 3.2.7 "Overall Fish Passage Survival". 1st paragraph, 3rd sentence. The text reads "Based on the small amount of information that is available, the average survival of adult spring-run chinook salmon and steelhead is estimated at between 77.8 percent and 88.9 percent for the entire Mid-Columbia River reach...". What is the cite for this information? The District is not aware of any methodology to measure adult survival.

65. Page 3-96, continuation of Section 3.3.2 "Water Quality", 1st full paragraph, 1st sentence. The text reads "Although extensive evaluations have been conducted under controlled or laboratory conditions, the effects of specific total dissolved gas levels on fish in a river environment is relatively unknown." This statement is not correct. The effects of total dissolved gas on fish has been extensively studied in the Mid-Columbia at as part of the 2000 Federal Columbia River Hydro-System biological opinions.

66. Page 3-109, Section 3.4.4 "Rare Plants". The text states that Ute ladies' tresses (*Spiranthes diluvialis*) do not occur in or near the immediate project area of the dams. This is not correct. Recently, a Ute ladies'-tresses was determined to be present in the Rocky Reach reservoir shoreline area. This hydrophilic orchid would be affected by drawdown or other actions that would remove its water source. P. Fielder, pers. comm.

67. Page 4-18, continuation of Section 4.2.2.1 "Rocky Reach Dam", 2nd paragraph, 2nd sentence. The text reads "Survival estimates for steelhead ranged from 87.0 percent to 111.9 percent ..." This is not correct. 111.9 percent should be 101.0 percent.

68. Page 4-18, continuation of Section 4.2.2.1 "Rocky Reach Dam", 3rd paragraph, 2nd sentence. The text reads "Under Alternative 1 however, there is no requirement to implement these additional measures." This is not correct. Under alternative 1 fish protection and enhancement measures can be implemented through the pending Mid-Columbia proceeding at FERC, and during relicensing.

69. Page 4-18, continuation of Section 4.2.2.1 "Rock Island Dam", 2nd paragraph, 2nd sentence. The text reads "Between 1995 and 1998, over 26,000 predatory ..." This

should be updated by replacing 1998 with 2000, and 26,000 with 34,000. West, T. 2001. Northern Pikeminnow (*Ptychocheilus oregonensis*) Population Reduction Program Rocky Reach and Rock Island Dams.

70. Page 4-20 continuation of "Adult Migration/Survival", 2nd full paragraph, 2nd sentence. The text reads "It is reasonable to assume that some portion of the adult bull trout populations pass through the turbines and spillways, either voluntarily or involuntarily, given their presence in the project area and use of project fishways." What is the citation for this information? Why is it reasonable to assume a correlation between presence of bull trout in the fishway and bull trout passing through turbines and spillways? The District is aware of no evidence supporting this statement.

71. Page 4-26, "Rocky Reach Dam", 2nd sentence. The text reads "As with the fishways at the Wells Dam, there is evidence to suggest that sockeye and summer-run chinook salmon experience passage delays in the fishway entrance pools of the Rocky Reach fishway." What is the citation for this information? The District is not aware of this information.

72. Page 4-27, Section 4.2.2.3 "Pacific Lamprey", 3rd sentence. The text reads "The only screens that are currently in operation at the Mid-Columbia River dams are at turbine units one through three at the Rocky Reach Dam." This is not correct. Screens are used only at turbine unites one and two at the Rocky Reach Dam.

73. Page 4-27, Section 4.2.2.3 "Pacific Lamprey", 4th sentence. Delete the phrase "although additional screens are currently not planned for future installation."

74. Page 4-31, "Adult Migration/Survival", 2nd paragraph last sentence. The text reads "Although the radio-telemetry technique is problematic for addressing adult passage survival, the study results are the best available data for determining potential project related affects." This sentence is not correct. Radio-telemetry is not a technique for addressing adult passage survival. It is a technique for addressing locations of adult fish. Currently, no protocol exists to measure adult survival. There is no data available to evaluate adult survival.

75. Page 4-31, "Adult Migration/Survival", 4th paragraph, 2nd sentence. The text reads "Based on their presence at the project and their migratory behaviors, it is likely that some portion of the population passes through the turbines and spillways, either voluntarily or involuntarily." What is the citation for this information? Why is it reasonable to assume a correlation between presence of bull trout in the fishway and bull trout passing through turbines and spillways? The District is aware of no evidence supporting this statement.

76. Page 4-34, "Rock Island Dam", 1st paragraph, 1st sentence. Delete "chiwawa hatchery". Rock Island's hatchery is referred to as the Eastbank Hatchery Complex.

77. Page 4-40 "Rocky Reach Dam", 2nd paragraph, 3rd sentence, and Page 4-41 "Rock Island", 2nd paragraph 3rd sentence. The text reads "For Alternative 3, the PUD would have the ultimate authority for determining the appropriate protection measures implemented in Phase I, while the Coordinating Committee would have a greater role during Phase II." As explained above in relation to other sections, the Coordinating Committee is the decision maker in Phase II. NMFS has retained the authority to enforce the incidental take permit outside the HCPs.

78. Page 4-59, Section 4.6.3.1 "Project Area". This text is not correct. Section V of the HCP titled "Reservoir as Habitat" clarifies the manner in which land use and permitting decisions on project lands occurs.

79. Page 4-72, Section 4.10.7 "Indian Trust Assets", 3rd paragraph, 5th sentence. The text reads "This would then affect whether the 9 percent no net impact would continue over the 50 year HCP terms." Reduction in use of the hatchery facilities means that the hatcheries would not produce fish to compensate for the full 7 percent of Unavoidable Project Mortality. HCP Section III.1. Nevertheless, No Net Impact can still be achieved as long as the PUDs provide the funding and capacity for the hatcheries. HCP Sections III.3. and 4.

80. Page 4-74, Section 4.10.14.1 "Wild and Scenic River Act". This section needs to be updated. On June 9, 2000, the Hanford Reach was declared a National Monument. 65 *Federal Register* 37253 (June 13, 2000).

81. Page 5-6, Chelan County PUD 2000 reference. The District objects to reference to comments provided to the "Pre-Decisional Review Draft, Biological Opinion, Interim Protection Plans for Operation of the Mid-Columbia River Hydroelectric Projects and Related Activities." These comments were provided to assist in editing a confidential, pre-decisional review document.

82. Page 6-1 "Glossary". It is the District's understanding that the glossary contained in the DEIS is not in any way intended to modify terms that are defined in the Endangered Species Act, NMFS' regulations, or the HCPs. The District has not reviewed the glossary, and reserves the right to latter object to the manner in which terms are defined in this DEIS.

83. Page 7-2, Section 7.3. Add the following local agencies: East Wenatchee Chamber of Commerce, Mayor of the City of Wenatchee, Chelan County Commissioners, and the Douglas County Commissioners.

84. Page 7-2, Section 7.4. Replace "Confederated Tribes of the Colville Reservation" with "Confederated Tribes and Bands of the Colville Indian Reservation." In the Umatilla name add "Indian" between "Umatilla" and "Reservation." Replace "Yakama Indian Nation" with "Confederated Tribes and Bands of the Yakama Indian Nation."

Conclusion

The District appreciates the opportunity to comment on the Draft Environmental Impact Statement for the incidental take permit applications proposed for the District's Rocky Reach and Rock Island Projects. The District encourages NMFS to expedite its processing of the incidental take permit applications, and authorize the issuance of the requested permits

Sincerely,

Malcolm C. McLellan
Attorney for
Public Utility District No. 1 of Chelan County

SURVIVAL ESTIMATES

FOR THE

ROCK ISLAND HYDROELECTRIC PROJECT

AND THE

ROCKY REACH HYDROELECTRIC PROJECT

Rock Island
Estimate of Juvenile Dam Passage Survival

FORMULA: The formula to estimate Juvenile Dam Passage Survival equals the route specific survival rate multiplied by the route specific passage rate for each passage route past the project.

Calculation of Juvenile Dam Passage Survival

Species	Powerhouse #1		Powerhouse 2		Spill		JDPS
	Survival Rate Of Turbines[1]	% of Fish using Turbines	Survival Rate Of turbines[1]	% of Fish using turbines	Survival Rate Of Spill	% of Fish using Spill	
Steelhead	.927	.051 (2 yr avg)	.942	.655 (2 yr avg)	.99	.295 (2 yr avg)	.956
Yearling Chinook[2]	.927	.087	.942	.671	.99	.242	.952
Sub-yearling Chinook[3]	.927	.091 (2 yr avg)	.942	.482 (2 yr avg)	.99	.437 (2 yr avg)	.971
Sockeye	.927	.134 (2 yr avg)	.942	.599 (2 yr avg)	.99	.269 (2 yr avg)	.955

Authority for Data

Species	Powerhouse 1		Powerhouse 2		Spill		JDPS

Executive Summary

The Upper Columbia Quantitative Analysis Report (QAR) process was established to provide decision makers with current assessments of the status of spring-run chinook salmon and steelhead runs returning to the Wenatchee, Entiat, and Methow River systems. Production of spring-run chinook salmon and steelhead from these three tributaries, along with the Okanogan River, constitutes the Upper Columbia River spring-run chinook salmon and the Upper Columbia River summer steelhead Evolutionarily Significant Units, respectively.[1] Upper Columbia River steelhead and spring-run chinook salmon were listed as endangered in 1997 and 1998, respectively. The purpose of this report is to provide hypothetical estimates of the relative risks of extinction under a range of alternative management and climatic/environmental scenarios and to estimate the survival gains necessary to meet interim recovery levels (IRLs) and reduce the risk of extinction to acceptable levels.

Simple population dynamics models were developed for Upper Columbia River spring-run chinook salmon (Wenatchee, Entiat, and Methow populations) and summer-run steelhead (Wenatchee/Entiat and Methow populations). Reconstructed spawner to spawner return ratios for historical years, estimated age at return data, and estimates of recent spawning escapements were used as input into a stochastic cohort run reconstruction (CRR) statistical model. The model was designed to generate hypothetical time trends in return levels and the effect of survival changes on those trends. Alternative assumptions regarding the effects of alternative future environmental conditions are analyzed for spring-run chinook salmon and the effectiveness of hatchery origin spawners are considered in the analysis for steelhead. Model development, assumptions, and simulations were reviewed by an analytical team consisting of representatives from Chelan, Douglas, and Grant County Public Utility Districts (PUDs); Bonneville Power Administration; Washington Department of Fish and Wildlife; Columbia River Inter-Tribal Fish Commission; and Columbia Basin Fish and Wildlife Authority.

The proposed Mid-Columbia Habitat Conservation Plan (HCP) incorporated a framework designed to address project impacts on migrating salmon and steelhead through the objective of no net impact.[2] The focus of the analyses described in this report is on identifying levels of life cycle survival improvements necessary for the two Endangered Species Act-listed stocks to be self-sustaining. The report includes specific assessments of the potential benefits of meeting the passage survival and habitat objectives of the proposed HCP for each of the five Mid-Columbia projects.[3] In the longer term, achieving conditions that result in survival levels high enough to support self-sustaining natural production is an important objective under the Endangered Species Act. The hatchery mitigation component of the HCP is

[1] The QAR Biological Requirements Workgroup identified three independent, viable populations of spring-run chinook salmon and steelhead in the Upper Columbia Basin (Wenatchee, Entiat, and Methow populations). Because of data limitations, Entiat and Wenatchee steelhead were modeled as a single group. Recovery goals for steelhead in the Okanogan system are deferred to the Upper Columbia Recovery Team.

[2] No net impact consists of two components: (1) 91% combined adult and juvenile project survival achieved by project improvement measures implemented within the geographic area of the project, and (2) 9% compensation for unavoidable project mortality provided through hatchery and tributary programs, with 7% compensation provided through hatchery programs and 2% compensation provided through tributary programs.

[3] While Grant County PUD is not part of the HCPs, for the purposes of assessing cumulative effects for this model, similar survival assumptions were made for each of the two Grant County PUD dams.

essential for achieving the mitigation objective of no net impact as a result of the Mid-Columbia hydropower projects.

Under National Marine Fisheries Service (NMFS) guidelines, hatchery production is explicitly not included in the assessment of long-term sustainability of a stock. However, hatchery supplementation can play a separate and important role in the overall approach to addressing particular Endangered Species Act-listed stock recovery issues. In the short term, hatchery supplementation can bolster weak stocks while survival improvement measures are implemented and play a major role in speeding up the rebuilding process.

The population models of Upper Columbia River spring-run chinook salmon and steelhead were used to explore five basic questions:

1. What are the relative risks of extinction to Upper Columbia River spring-run chinook salmon under alternative assumptions about future environmental conditions?

2. What are the relative risks of extinction to Upper Columbia River steelhead under alternative assumptions about the effectiveness of hatchery origin spawners?

3. How much improvement in survival across the life history of a particular run is necessary to meet extinction risk criteria and interim recovery levels?

4. What benefits in terms of life cycle survival would be gained by meeting the specific survival improvement goals in the Mid-Columbia HCP?

5. Assuming that the survival objectives set forth in the proposed Mid-Columbia HCP and the Federal Columbia River Power System Biological Opinion are met, would the cumulative improvement in survival meet or exceed population-specific survival improvement needs?

It is important to note that although the proposed Mid-Columbia HCP is intended to improve the survival of Upper Columbia River chinook salmon and steelhead, it is not intended, by itself, to be the only action responsible for meeting Evolutionarily Significant Unit recovery objectives. In determining whether or not a particular action jeopardizes the continued existence of a listed Evolutionarily Significant Unit, NMFS determines "…whether the species can be expected to survive with an adequate potential for recovery under the effects of the proposed or continuing action, the effects of the environmental baseline, and any cumulative effects, and considering measures for survival and recovery specific to other life stages."[4]

Because future environmental/climatic conditions cannot be accurately predicted, information was used from three different sets of years within the chinook salmon data series to capture a possible range of future conditions. Spawner-return data for the Upper Columbia River spring-run chinook salmon runs date back to about 1960. Annual spawner return rates were generally higher for broods originating in the 1960s than in later years. Return levels for broods originating in the early 1990s included several of the lowest rates in the historical time series. Model runs using three different sets of spawner return data

[4] 2001 Federal Columbia River Power System Biological Opinion, Section 1.3.

from the historical series were used to characterize the relative extinction risks and survival needs under alternative environmental conditions.

Model runs incorporating the average and variance in spawner return rates across the entire historical series (1960 to 1994 brood years) represent an assumption that future environmental conditions are best represented by the longest historical series that can be generated and will result in some good survival years (similar to those observed in the 1960s) and some poor survival years (similar to the 1980s through the mid-1990s). This scenario would encompass assumptions that salmon survivals are strongly influenced by long-term (30- to 50-year) cycling in ocean/climatic conditions. Model runs incorporating the 1980 to 1994 period capture a time of relatively poor environmental/climatic conditions. If one assumes that these poor environmental/climatic conditions will continue into the future (a conservative view), then results based on the time series 1980 to 1994 would be most applicable. The period 1970 to 1994 may reflect an average condition that falls between the poor conditions represented by the 1980 to 1994 data series and the better conditions of the 1960 to 1994 series. The spawner-return data series for Upper Columbia River steelhead is relatively short (1976 to 1994); therefore, no attempt to generate alternative future survival and extinction risks for steelhead was made for spring-run chinook salmon.

The results from these simulations should not be viewed as specific predictions of future conditions or stock status. Rather, these models are tools intended to illustrate the potential response of the population to a range of future scenarios given a set of assumptions regarding population dynamics. While those assumptions are based on the best available information, there is considerable uncertainty associated with many of the estimates. This report includes sensitivity analyses designed to illustrate the influence of uncertainty in selected key assumptions on model results.

Current Extinction Risks

The CRR model estimated the relative risk of extinction of spring-run chinook salmon populations at 24, 48, and 100 years and for steelhead at 25, 50, 75, and 100 years.[5] The majority of the extinction risk assessments described in this report are expressed in terms of absolute extinction—defined as the probability that chinook salmon or steelhead populations fall to one or fewer spawners in 5 or more consecutive years. Given the uncertainty associated with productivity at extremely low levels of escapement, quasi-extinction risk assessments were also applied to chinook salmon model populations. Quasi-extinction risk was estimated as the probability that chinook salmon runs would fall to 50 or fewer spawners in the Methow and Wenatchee Basins and 30 or fewer in the Entiat Basin for 5 or more consecutive years.[6] For each scenario analyzed, the model was run for 1,000 iterations. Relative extinction risk at each of the selected time intervals was expressed as the percentage of 1,000 runs projected to be at or below the selected extinction level.

Extinction risk assessments based on simple population models are sensitive to assumptions regarding the average and distribution of spawner return rates and to the starting population size. Spawner return

[5] Estimated returns of chinook salmon to the Upper Columbia tributaries were based on annual redd counts dating back to the late 1950s and early 1960s. Estimated returns of steelhead were based on dam counts.

[6] The risk criteria are described in the QAR Biological Requirements Report (Ford et al. 2001).

rates (geometric mean and variances) were calculated for the alternative time series described above. Two alternative estimates of starting population size were used. Under the first approach, recent (1995 to 1999) average spawning escapement estimates were used as the basis for starting population size. Projections of the trend in spawning escapements from the initial level were generated by the simple population model using the spawner return rate estimates as a basis for generating production from each spawning year. A second starting point was used to simulate extinction risks given initial achievement of recovery abundance levels as a result of supplementation, but without long-term improvement in mean spawner to spawner return levels. Under this set of scenarios, the starting point for the analyses were initial spawning escapements at the IRLs recommended for each of the listed Upper Columbia River populations.[7]

Spring-Run Chinook Salmon Extinction Risks

Extinction risks varied among the three Upper Columbia River spring-run chinook salmon population areas. In general, the modeling analysis indicated that the Wenatchee River population has the highest current risk of extinction of the three populations analyzed. Extinction risk levels were sensitive to the time period used to derive survival/production characteristics.

Annual return rates since 1980 have been highly variable, and until brood year 1995, have included the lowest estimated return per spawner rates in the record. Assuming that conditions into the future will continue at levels associated with the 1980 to 1994 brood year data series results in high probabilities of extinction in 50 to 100 years for all Upper Columbia River spring-run chinook salmon stocks (Table 1).

TABLE 1. PROBABILITY OF EXTINCTION (ZERO FISH) FOR UPPER COLUMBIA RIVER SPRING-RUN CHINOOK AT 24-, 48-, AND 100-YEAR INTERVALS[1]

POPULATION	BASE PERIOD	EXTINCTION RISK AT:		
		24 YEARS	48 YEARS	100 YEARS
Wenatchee	1960-1994	0%	0%	2%
	1970-1994	1%	19%	73%
	1980-1994	15%	57%	98%
Entiat	1960-1994	0%	0%	0%
	1970-1994	2%	10%	47%
	1980-1994	16%	83%	99%
Methow	1960-1994	0%	0%	5%
	1970-1994	2%	24%	72%
	1980-1994	1%	15%	50%

[1] This analysis assumed that environmental conditions would be similar to those experienced during three base periods (1960-1994, 1970-1994, and 1980-1994).

[7] Interim Recovery Levels are described in the QAR Biological Requirements Report (Ford et al. 2001).

Assuming that future conditions are best represented by the historical series extending back to brood year 1970 generally reduces extinction risks in the Wenatchee and Entiat analyses. For the Methow analysis, extending the series back to 1970 did not substantially change the projected extinction risk. Spawning escapements for spring-run chinook salmon in years 2000 and 2001 indicated relatively high return rates for the 1995 and 1996 brood years. Incorporating these brood years into the extinction analysis resulted in projections similar to those of the 1970 to 1994 data set. Assuming future conditions would include survivals like those observed in the early 1960s results in a large decrease in extinction risks relative to the assumption that survivals will remain at the lower levels seen since 1980. However, to meet extinction risk criteria, improvements in average population growth rate would still be necessary.

The extinction risk projections described above were generated assuming that the geometric mean return per spawner and the observed level of year to year variation about that mean for each historical series would continue to apply into the future. There is uncertainty associated with the estimates of trend. A simple modeling analysis using the Wenatchee spring-run chinook salmon data series was conducted to assess the effect of uncertainty in the trend estimate on the projected extinction risk. Assuming that the estimated geometric mean trend continues, the point estimate of extinction risk using the 1980 to 1994 Wenatchee data series was 98 percent at 100 years. Incorporating uncertainty in the historical trend estimate generated a range about that point estimate, but a high proportion of the results projected relatively high risks of extinction. For example, 90 percent of the runs based on the 1980 to 1994 data set incorporating uncertainty projected 100-year extinction probabilities of 31 percent or higher. Using the 1970 to 1994 data set, approximately 75 percent of the runs projected 100-year extinction rates of 31 percent or higher.

Steelhead Extinction Risks

As described above, more limited trend data are available for Upper Columbia River steelhead. The parameters for the steelhead extinction risk model were derived from the 1986 to 1992 brood year data sets for the Wenatchee/Entiat and Methow steelhead runs. A significant proportion of returns to these areas are of hatchery origin. The relative effectiveness of hatchery origin spawners is a key scientific uncertainty. Extinction risk estimates were generated for a range of possible relative effectiveness values for naturally spawning fish of direct hatchery origin. As was the case with spring-run chinook salmon, the extinction risk assessments for steelhead were designed to evaluate the potential for runs to sustain production if hatchery supplementation were to be discontinued. The level of extinction risk was substantially influenced by assumptions regarding the historical effectiveness of hatchery contributions relative to spawners of natural origin. Extinction risk projections at 100 years were estimated to be approximately 28 to 35 percent under the assumption of low (25 percent) relative effectiveness of spawners. Under the assumption that the relative effectiveness of hatchery spawners is 50 percent or greater relative to wild fish, the projected extinction risks at 100 years for both groups was 99 to 100 percent (Table 2).

TABLE 2. PROBABILITY OF EXTINCTION (ZERO FISH) FOR UPPER COLUMBIA RIVER SUMMER-RUN STEELHEAD AT 25-, 50-, 75-, AND 100-YEAR INTERVALS[1]

POPULATION	THEORETICAL SPAWNER EFFECTIVENESS	EXTINCTION RISK AT:			
		25 YEARS	50 YEARS	75 YEARS	100 YEARS
Wenatchee/Entiat	25%	0%	0%	8%	35%
	50%	0%	26%	99%	100%
	75%	0%	80%	100%	100%
	100%	0%	99%	100%	100%
Methow	25%	0%	3%	11%	28%
	50%	0%	60%	97%	99%
	75%	3%	96%	100%	100%
	100%	10%	99%	100%	100%

[1] This analysis assumes that (1) hatchery augmentation is immediately discontinued, (2) survival conditions experienced during the 1976-1992 base period continue for the next 100 years, and (3) theoretical hatchery spawner effectiveness was 25, 50, 75, or 100 percent of naturally produced spawners.

Supplementation Scenarios

Simplified supplementation scenarios for Upper Columbia River spring-run chinook salmon were evaluated with the CRR model. Supplementation has the potential to accelerate the return of spawning numbers to IRLs. Under the assumption that the Evolutionarily Significant Units should be capable of sustaining themselves without supplementation, model runs were made under the assumption that run sizes were boosted to the IRL through the use of supplementation and then supplementation was discontinued and the risk of extinction was calculated as described above. Under the conservative assumption that population survival rates similar to those observed in the 1980 to 1994 data set continues, longer-term (e.g., 100-year) risks were nearly as high for the Wenatchee and Entiat populations as for the runs starting from recent averages. However, the long-term (100-year) risks for the Methow populations were substantially reduced (less than 21 percent) when starting the population at the IRL.

Survival Changes Needed to Meet Extinction Risk and IRL Criteria

The CRR model was also used to generate estimates of the average change in survival over the life cycle[8] needed to meet specific extinction risk criteria (e.g., less than a 5 percent risk of extinction as a result of year to year environmental variability and meeting IRL escapement objectives). Meeting the recommended IRL escapement criteria requires a larger increase in survival than meeting the direct

[8] Changes necessary to meet particular risk criteria are expressed in terms of survival in this paper. These increments can be translated into changes in population growth rate, λ, using an estimate of average generation time for the particular population of interest.

extinction risk criteria for all of the populations. The objective of maintaining average escapements at IRL or above is to provide protection against demographic, environmental, and genetic risk factors.

Spring-Run Chinook Salmon

Assuming that background survival rates were to continue at the relatively poor rates observed during the 1980 to 1994 period (the most conservative assumption), the modeled Wenatchee spring-run chinook salmon population would need a survival improvement of 75 percent to reduce the projected extinction risk at 100 years to below 5 percent. The necessary survival improvement using the 1970 to 1994 data series is 35 percent, and no improvement is necessary to meet this metric using the 1960 to 1994 data series. To meet the recovery escapement criteria (IRL) at 48 years, a survival improvement of 170 percent would be needed for this population using the 1980 to 1994 data series. Meeting the IRL criteria at 100 years would require a survival increase of 155 percent under the 1980 to 1994 assumptions. If long-term background survivals are similar to the 1970 to 1994 series, the requirements would drop to 92 percent and 110 percent to meet IRL criteria at 48 and 100 years, respectively. Assuming that the distribution of future survival is represented by the longest time series (the range observed since 1960), required survival increases of 40 percent and 15 percent would be needed to meet IRL criteria for the 48-year and 100-year time periods (Table 3).

Model runs based on the Methow spring-run chinook salmon data set indicated that similar levels of improvement would be required. Assuming that the long-term series of spawner/return estimates (1960 to 1994 brood years) represents future conditions, a 19 percent increase in life cycle survival would be required to reduce the projected extinction risk at 100 years to below 5 percent. A 48 percent increase in survival would be needed to meet and maintain IRL criteria within 100 years, and a 52 percent increase would be needed to meet IRL criteria within 48 years. Assuming that the relatively poor survival conditions indicated by the 1980 to 1994 data series are representative of the future, meeting the 100-year extinction risk criteria would require a 32 percent increase in life cycle survival, and meeting the IRL levels would require an increase of 95 percent (within 100 years) or 105 percent (within 48 years). Results for the Methow using the intermediate 1970 to 1994 time series were similar to the 1980 to 1994 results (see Table 3).

Projections based on the Entiat spring-run chinook salmon data set followed similar patterns. Under the assumption that the longer-term data set (1960 to 1994 brood years) is representative of future environmental conditions, no additional survival improvements would be required to reduce the projected extinction risk to 5 percent. IRL levels would be achieved with increases of 22 percent (48-year target) or 17 percent (100-year target). Assuming that the 1980 to 1994 data series is most representative of future conditions, model projections indicate that a survival improvement of 57 percent is needed to reduce the 100-year extinction risk to 5 percent. Survival improvements of 95 percent or 105 percent would be required to meet IRL objectives at 100 years or 48 years, respectively. Using the 1970 to 1994 data to represent future conditions results in a projected survival improvement requirement of 18 percent to meet extinction risk criteria at 100 years. Meeting IRL levels under this scenario requires life cycle survival improvements of 52 percent (100-year target) or 62 percent (48-year target) (see Table 3).

TABLE 3. PROJECTED CHANGE IN SPAWNER TO SPAWNER SURVIVAL RATES FOR UPPER COLUMBIA RIVER SPRING-RUN CHINOOK SALMON NEEDED TO REDUCE THE PROBABILITY OF EXTINCTION TO LESS THAN 5 PERCENT AND TO HAVE A GREATER THAN 50 PERCENT PROBABILITY OF EXCEEDING THE INTERIM RECOVERY LEVEL WITHIN 100 YEARS[1]

POPULATION	BASE PERIOD	SURVIVAL INCREASE REQUIRED TO REDUCE EXTINCTION RISK TO LESS THAN 5% AT:		SURVIVAL INCREASE REQUIRED TO HAVE A GREATER THAN 50% PROBABILITY OF EXCEEDING IRL AT:	
		24 YEARS	100 YEARS	48 YEARS	100 YEARS
Wenatchee	1960-1994	0%	0%	40%	15%
	1970-1994	0%	35%	110%	92%
	1980-1994	7%	75%	170%	155%
Entiat	1960-1994	0%	0%	22%	17%
	1970-1994	0%	18%	62%	52%
	1980-1994	12%	57%	112%	100%
Methow	1960-1994	0%	19%	52%	48%
	1970-1994	0%	34%	100%	95%
	1980-1994	0%	32%	105%	95%

[1] This analysis assumed that environmental conditions would be similar to those experienced during three base periods (1960-1994, 1970-1994, and 1980-1994) and that the population started at recent average (1980-1994) escapement levels.

The improvement levels necessary to meet short-term risks to extinction due to the compound effects of year to year environmental variation are less then the levels required to meet IRLs for each model population. In general, the survival improvements to meet 48-year and 100-year extinction risk criteria are approximately one-third to one-half of the improvement levels required to meet IRL criteria.

Steelhead

The CRR model was used to estimate the improvement in life cycle survival needed to meet the basic extinction risk criteria described above. The results were substantially influenced by assumptions regarding the effectiveness of hatchery spawners in contributing to natural production. Model runs incorporating the Methow steelhead data series required the highest levels of improvement in life cycle survival to meet the extinction risk criteria.

Under the assumption that hatchery steelhead spawners have been contributing equally with natural returns to production, the Methow model runs indicated that an increase of 152 percent in survival over the life cycle would be required to meet the 100-year extinction risk criteria, and an improvement of 265 percent[9] would be needed to achieve the IRL criteria at 100 years. Assuming that hatchery spawners

[9] For the steelhead model runs, recent average escapement levels (including hatchery fish) have been relatively high. There was little difference in the projected survival increases to meet IRL levels at 48 years versus 100 years.

were 25 percent as effective as returning adults of natural parentage, the survival change needed to meet the 100-year direct extinction risk criteria was 15 percent, and the change needed to meet IRL objectives was 55 percent. The survival changes needed to meet the 100-year risk criteria under the 50 percent and 75 percent effectiveness assumptions were 70 percent and 115 percent. Meeting the IRL targets under the 50 percent and 75 percent effectiveness assumptions required improvements of 135 percent and 200 percent, respectively (Table 4).

TABLE 4. PROJECTED CHANGE IN SPAWNER TO SPAWNER SURVIVAL RATES FOR UPPER COLUMBIA RIVER STEELHEAD NEEDED TO REDUCE THE PROBABILITY OF EXTINCTION TO LESS THAN 5 PERCENT AND TO HAVE A GREATER THAN 50 PERCENT PROBABILITY OF EXCEEDING THE INTERIM RECOVERY LEVEL WITHIN 100 YEARS[1]

POPULATION	THEORETICAL SPAWNER EFFECTIVENESS	SURVIVAL INCREASE REQUIRED TO REDUCE EXTINCTION RISK TO LESS THAN 5% AT:		SURVIVAL INCREASE REQUIRED TO HAVE A GREATER THAN 50% PROBABILITY OF EXCEEDING IRL AT:	
		24 YEARS	100 YEARS	48 YEARS	100 YEARS
Wenatchee/ Entiat	25%	0%	12%	50%	50%
	50%	0%	45%	95%	95%
	75%	0%	67%	120%	120%
	100%	0%	87%	160%	160%
Methow	25%	0%	15%	55%	55%
	50%	0%	70%	140%	135%
	75%	0%	115%	210%	200%
	100%	0%	152%	265%	265%

[1] This analysis assumed that (1) hatchery augmentation is immediately discontinued, (2) survival conditions experienced during the 1976-1992 base period continue for the next 100 years, and (3) theoretical hatchery spawner effectiveness was 25, 50, 75, or 100 percent of naturally produced spawners.

Projected survival improvements for the Wenatchee/Entiat population grouping were lower, but were still substantial. Meeting the direct extinction risk criteria of 5 percent risk or less by 100 years required 87 percent improvement in life cycle survival under the assumption that hatchery spawners were equally effective as naturally produced spawners. Meeting the IRL targets with this assumption required a 160 percent improvement in survival. Under the assumption that hatchery spawners were only 25 percent as effective as naturally produced spawners, the survival improvements needed to meet the 100-year extinction risk criteria and the IRL level were 12 percent and 50 percent, respectively. Assuming intermediate hatchery effectiveness assumptions of 50 percent and 75 percent, an additional survival improvement of 45 percent and 67 percent would be necessary to meet the 100-year risk criteria and improvements of 95 percent and 120 percent would be necessary to meet the IRL targets, respectively (see Table 4).

Upper Columbia River steelhead returns have been predominantly of hatchery origin since at least the late 1970s. The relative reproductive effectiveness of hatchery spawners versus returning adults from

naturally spawning parents is unknown for Upper Columbia River steelhead. Results of the modeling exercise support the contention that the relative effectiveness of hatchery spawners is a key scientific uncertainty relative to the level of survival improvements necessary to meet extinction risk and recovery criteria for the wild populations.

Sensitivity Analyses

The spring-run chinook salmon version of the CRR model was used in a series of analyses to probe the sensitivity of results (extinction risks and the life cycle survival improvement necessary to meet IRL criteria) to key assumptions.

Incorporating Preliminary Estimates of 1999 to 2001 Returns

Preliminary estimates of 1999 to 2001 returns were used to expand the 1980 to 1994 brood year data series to include brood years 1995 and 1996 for the Wenatchee and Methow spring-run chinook salmon data sets. Returns from these two brood years were significantly higher than for the recent series. The expanded data sets were analyzed with the CRR model. Extinction risks and the incremental improvements in survival necessary to meet survival and IRL criteria were reduced to approximately the same levels as were indicated by analyses of the 1970 to 1994 data sets. This analysis supports the idea that the results of the 1980 to 1994 data series analysis should be viewed as the most conservative of the three data series analyzed.

Carrying Capacity

The estimated increase in survival is sensitive to assumptions regarding carrying capacity of the systems. If carrying capacity is substantially higher than the IRL level, the survival improvement required to rebuild from recent average escapements to IRL would be lower. For example, the requirement to meet the IRL escapement criteria for the Wenatchee (assuming future survivals are represented by the conservative1980 to 1994 data series) would be 170 percent assuming that maximum smolt production is reached at an escapement of 4,000 (approximately equal to the IRL level of 3,750). The survival improvement necessary to reach IRL criteria would drop below 100 percent if the carrying capacity is roughly double the IRL level (7,500). If the carrying capacity (spawning level producing maximum smolt output) is very high relative to the IRL, the required survival improvement would be reduced to approximately 75 percent.

Stock-Recruit Model

The population modeling described in this paper was based largely on a simple 'broken stick' model relating productivity to spawning population size. Under this approach, production per spawner is constant up to a carrying capacity threshold. At escapements above that threshold, average production is constant. An alternative population function, the Ricker spawner/recruit function, has been fit to historical data from the Upper Columbia stocks (Schaller et al. 2000). The CRR model was modified to implement the Ricker function derived from the 1970 to 1994 brood year spawner/return series. Using the Ricker function resulted in lower projected extinction risks relative to the broken stick model assuming the 1970 to 1994 average survivals would continue. Reducing survivals to the equivalent of the more conservative 1980 to 1994 levels resulted in high extinction risk probabilities, similar to the broken stick model. Achieving the IRL levels took higher increments of survival improvements than were required using the broken stick model.

Survival Changes at Different Life History Phases

The sensitivity of average annual population growth rate to changes in mortality at specific phases in the life cycle showed a similar pattern to Snake River analyses, with a couple of exceptions. The Snake River populations and the Upper Columbia populations exhibit high mortality rates in the egg to smolt and the estuary to ocean adult phases. Shift of 10 percent mortality to survival could theoretically increase survival rates 2 to 3 times. However, the resulting survivals would be higher than smolt production rates that are associated with relatively healthy stocks. The feasibility of particular actions to achieve survival increases that are mathematically and biologically possible is a third important consideration.

Potential Survival Change from HCP

Projecting survival changes associated with achieving the HCP survival goals depends on assumptions regarding historical passage survival through the projects. Little direct information on historical reach survival is available. Study groups released in the mid-1980s were used to calibrate a simple model of passage survival to estimates of annual arrival timing and spill at each project. Assuming base period survival rates similar to those reported during the system survival studies conducted in the 1980s resulted in estimates of per project survival of 86 to 88 percent. Achieving the HCP goals (91 percent combined adult and juvenile project survival) would increase average juvenile passage survival to 93 percent per project, or 16 to 25 percent for steelhead and 21 to 35 percent for spring-run chinook salmon (range is for three to five projects).[10]

Potential Survival Change from Dam Removal

For comparison purposes, an estimate of what juvenile survivals may have been through the Mid-Columbia reach in the absence of the hydroelectric dams was generated (assuming that dams were either not built in the first place or were removed without any negative environmental consequences). Passive integrated transponder (PIT) tag survival data from Snake River studies (e.g., Smith et al. 1998) were used to estimate downstream migration mortality rates for juvenile spring-run chinook salmon and steelhead migrating through free-flowing reaches within the Snake River system. The results were applied to each population grouping by multiplying the number of kilometers from the tributary of origin to the Priest Rapids Dam site against the per kilometer survival rate from the Snake River studies. Estimated survivals to a point below the present Priest Rapids Dam varied from a low of 93 percent (Methow steelhead) to a high of 97 percent (Wenatchee River spring-run chinook salmon). This range represents a 40 to 84 percent increase in survival over the base periods used in this analysis.

Under the assumption that the 1980 to 1994 survival conditions continue, achievement of the survival improvements, up to the level estimates for free-flowing conditions (i.e., if the dams were removed), would not meet the IRL criteria for any of the three spring-run chinook salmon stocks. Assuming that the equivalent of free-flowing passage through the Mid-Columbia reach is achieved and that the 1970 to 1994 survival conditions continue, the IRL criteria would be met for the Entiat spring-run chinook

[10] Upper Columbia River Evolutionarily Significant Units are more responsive to changes in passage survival at the series of mainstem dams due to the reliance on in-river migration since barging from McNary was curtailed in 1995.

salmon population but not for the Wenatchee and Methow spring-run chinook salmon populations. Assuming that the 1960 to 1994 survival conditions continue, the 100-year IRL criteria would be met for all populations of Upper Columbia River chinook salmon.

Summary: Potential Survival Improvements Versus Requirements

The estimated improvements in passage survival associated with achieving the objectives expressed in the proposed Wells, Rocky Reach, and Rock Island HCPs are directly comparable to the projected life cycle survival improvement requirements generated by the historical analyses described above.

Spring-Run Chinook Salmon

For spring-run chinook salmon, achieving the HCP objectives would result in sufficient survival improvements to meet the projected needs under the assumption that future return per spawner patterns are represented by the 1960 to 1994 brood year series, with the possible exception of meeting IRL criteria for the Wenatchee (0 to 14 percent projected improvement needed after HCP contribution).

Projections based on the Wenatchee spring-run chinook salmon data set indicate that even under the most optimistic scenarios modeled regarding future survival rates and the effectiveness of supplementation, additional survival improvements beyond those projected for proposed HCP actions would be necessary to achieve extinction risk/recovery criteria if the conditions observed during the 1980 to 1994 data series continue. Under these assumptions, an additional increase in life cycle survival of approximately 37 percent would be required to meet the 5 percent extinction risk threshold at 100 years. Increasing geometric mean escapements to IRL levels would require an additional survival improvement of 30 to 54 percent, depending upon assumptions and time frames.

Model runs based on the Methow spring-run chinook salmon data sets projected that the estimated survival improvements attained by meeting the proposed Mid-Columbia HCP objectives exceeded the required improvements to reduce direct extinction risks below the 5 percent level at 100 years under all three assumptions about future conditions. If future conditions are represented by the 1960 to 1994 data series, achieving the survival improvements associated with the HCP criteria would also cover the improvements needed to meet IRL objectives. However, meeting the longer-term IRL criteria at 48 or 100 years would require additional survival improvements beyond those associated with meeting the Mid-Columbia HCP passage objectives under the remaining future scenarios. Under the assumption that the relatively low return rates observed for 1980 to 1994 broods are representative of the future, additional survival improvements of 31 to 38 percent would be needed. Similar improvement levels would be required if the 1970 to 1994 data series is assumed to be representative of future conditions (Table 5).

For the Entiat spring-run chinook salmon population, achieving the potential survival improvements associated with meeting the proposed HCP objectives would cover the projected improvements required to reduce direct extinction risks to below 5 percent at 100 years under the 1960 to 1994 and the 1970 to 1994 future scenarios. An additional improvement in life cycle survival of approximately 12 percent would be required to meet the 5 percent extinction risk criterion under the more conservative 1980 to 1994 projections. Achieving the survival improvements associated with the proposed HCP objectives would also meet IRL requirements under the assumption that 1960 to 1994 population return per spawner rates are representative of the future. Using the 1970 to 1994 series, an additional survival increment of 9 to 16 percent would be required to meet IRL levels. If the 1980 to 1994 data series is

TABLE 5. PROJECTED CHANGE IN SPAWNER TO SPAWNER SURVIVAL FOR UPPER COLUMBIA RIVER SPRING-RUN CHINOOK SALMON REMAINING TO REDUCE THE PROBABILITY OF EXTINCTION TO LESS THAN 5 PERCENT AND TO HAVE A GREATER THAN 50 PERCENT PROBABILITY OF EXCEEDING THE INTERIM RECOVERY LEVEL WITHIN 100 YEARS[1]

		SURVIVAL INCREASE REQUIRED TO REDUCE EXTINCTION RISK TO LESS THAN 5% WITH:			SURVIVAL INCREASE REQUIRED TO HAVE A GREATER THAN 50% PROBABILITY OF EXCEEDING IRL WITH:		
POPULATION	BASE PERIOD	NO ACTION	HCP	HCP + FEDERAL BIOLOGICAL OPINION	NO ACTION	HCP	HCP + FEDERAL BIOLOGICAL OPINION
Wenatchee	1960-1994	0%	0%	0%	15%	0%	0%
	1970-1994	35%	5%	0%	92%	48%	36%
	1980-1994	75%	37%	31%	155%	99%	83%
Entiat	1960-1994	0%	0%	0%	17%	0%	0%
	1970-1994	18%	0%	0%	52%	9%	0%
	1980-1994	57%	12%	7%	100%	43%	31%
Methow	1960-1994	19%	0%	0%	48%	0%	0%
	1970-1994	34%	0%	0%	95%	31%	20%
	1980-1994	32%	0%	0%	95%	31%	20%

[1] This analysis assumed that (1) environmental conditions will be similar to those experienced during three base periods (1960-1994, 1970-1994, and 1980-1994), (2) the population started at recent average (1980-1994) escapement levels, and (3) delayed mortality from Federal transportation would be 20 percent (D = 0.8). Three action alternatives were evaluated, including (1) No Action, (2) HCP, and (3) HCP plus Federal biological opinion actions.

more representative of the average and range of future conditions, improvements of approximately 43 percent and 51 percent would be required to meet IRL targets at 100 years and 48 years, respectively (see Table 5).

In summary, if future environmental conditions resemble the longer 1960 to 1994 or 1970 to 1994 data sets rather than the more conservative 1980 to 1994 data set, then the levels of additional survival needed for recovery metrics are reduced substantially or eliminated in certain scenarios. For spring-run chinook salmon, the addition of 2000 and 2001 adult returns (1995 and 1996 brood years) to the 1980 to 1994 brood year data yielded mean spawner/return rates similar to those of the 1970 to 1994 data series. This suggests that the 1970 to 1994 data set may best represent future environmental conditions for predicting extinction risks and the probability of achieving IRL criteria.

Steelhead

For both of the modeled steelhead populations (the Wenatchee/Entiat and the Methow), gaining the survival improvements associated with meeting the proposed HCP objectives would cover the required changes for the 100-year extinction criteria only under the assumption that hatchery effectiveness was 0.25 or less. Model runs incorporating the 0.5, 0.75, and 1.0 effectiveness assumptions all predict that

additional improvements in survival would need to be realized to meet the 100-year risk criteria. Additional survival improvements would also be required to meet IRL levels under any of the assumptions regarding hatchery effectiveness (Table 6).

TABLE 6. PROJECTED CHANGE IN SPAWNER TO SPAWNER SURVIVAL FOR UPPER COLUMBIA RIVER SUMMER STEELHEAD REMAINING TO REDUCE THE PROBABILITY OF EXTINCTION TO LESS THAN 5 PERCENT AND TO HAVE A GREATER THAN 50 PERCENT PROBABILITY OF EXCEEDING THE INTERIM RECOVERY LEVEL WITHIN 100 YEARS[1]

Population	Theoretical Hatchery Effectiveness	Survival Increase Required to reduce extinction risk to less than 5% with:			Survival Increase Required to have a greater than 50% probability of exceeding IRL with:		
		No Action	HCP	HCP + Federal Biological Opinion	No Action	HCP	HCP + Federal Biological Opinion
Wenatchee/ Entiat	25%	12.0%	0.0%	0.0%	50.0%	22.0%	23-20%
	50%	45.0%	18.0%	24-21%	95.0%	59.0%	61-54%
	75%	67.0%	36.0%	58-51%	120.0%	79.0%	82-72%
	100%	87.0%	52.0%	86-76%	160.0%	111.0%	116-102%
Methow	25%	15.0%	0.0%	0.0%	55.0%	12.0%	13-11%
	50%	70.0%	23.0%	19-16%	135.0%	70.0%	73-64%
	75%	115.0%	56.0%	33-37%	200.0%	117.0%	122-108%
	100%	152.0%	83.0%	54-48%	265.0%	164.0%	171-151%

[1] This analysis assumed that (1) hatchery augmentation is immediately discontinued, (2) survival conditions experienced during the 1976-1992 base period continue for the next 100 years, and (3) historical hatchery spawner effectiveness was 25, 50, 75, or 100 percent of naturally produced spawners. Three action alternatives were evaluated, including (1) No Action, (2) HCP, and (3) HCP plus Federal biological opinion actions. The latter is expressed as a range reflecting alternative assumptions regarding the relative survival of transported fish (D = 1.0 or 0.8).

Meeting Mid-Columbia HCP and Federal Columbia River Power System Objectives

The draft Federal Columbia River Power System Biological Opinion calls for implementation of an aggressive set of improvements to in-river survival at lower river projects affecting the Upper Columbia River. The extent to which those improvements in survival represent a net increase in survival over the average for the base periods used in these assessments is dependent upon assumptions regarding delayed mortality of transported fish.[11] The draft Federal Columbia River Power System Biological Opinion also characterizes the level of off-site mitigation by the Federal action agencies given the continuing survival impacts of operating the hydropower system.

[11] Before 1995, a portion of the smolt run arriving at McNary was collected and transported to below Bonneville Dam.

Spring-Run Chinook Salmon

Achieving the combined survival improvement increments associated with the proposed HCP and the Federal Columbia River Power System Biological Opinion (direct and off-site mitigation changes) would exceed the changes needed to meet the 100-year extinction risk criteria for all three stock groupings with two exceptions. Under the most conservative data set (1980 to 1994 brood years), the Wenatchee and Entiat spring-run chinook salmon populations are projected to need an additional 31 percent and 7 percent increase, respectively, in survival to meet this criteria. The combination of improvements would similarly exceed the projected requirements to meet IRL objectives for each of the populations assuming that 1960 to 1994 environmental conditions persist into the future. Under the assumption of 1970 to 1994 conditions, an additional 0 to 36 percent increase in survival would be required to meet the 100-year IRL criteria. Under the most conservative assumption of future environmental conditions (1980 to 1994 brood years), an additional 20 to 83 percent improvement in survival would be required to meet the criteria for each of the modeled populations.

Steelhead

Again, assumptions regarding the relative effectiveness of hatchery origin fish in contributing to natural production have a significant impact on the results. The combined improvements from achieving the proposed HCP and Federal Columbia River Power System objectives would exceed the requirements to meet the 100-year extinction risk criteria for both stock groupings if hatchery spawner effectiveness has been 0.25 that of naturally produced spawners. Additional survival improvements would be necessary to reduce the risk to 5 percent or less if hatchery effectiveness is assumed to be 0.5 to 1.0. The additional survival needed to meet these criteria for Wenatchee/Entiat and Methow steelhead ranges from 21 to 86 percent and from 16 to 54 percent, respectively.

Model runs representing both of the stock groupings indicate that, even with the assumption that the HCP and Federal Columbia River Power System survival improvements are fully realized, additional survival improvements would be needed to achieve the 48- and 100-year IRL criteria for any of the hatchery spawner effectiveness scenarios. For Wenatchee/Entiat steelhead, additional survival improvements of 20 percent to 116 percent would be necessary to achieve the 100-year IRL criteria. An additional survival improvement of 11 percent to 171 percent would be required to achieve the 100-year IRL criteria (see Table 6).

Figure F-10. Energy Loss on a Monthly Basis – Wells Project

Given the forecasted relatively flat spill characteristics throughout the day, lost capacity is approximately equal to the lost energy in aMWs. For example, it would require 100 megawatts of capacity generating 100 percent of the time to generate a block of energy of 100 aMW. The average spill for Alternative 2 for Wells, Rocky Reach, and Rock Island represents a 40 percent spill from March 15 through September 15.

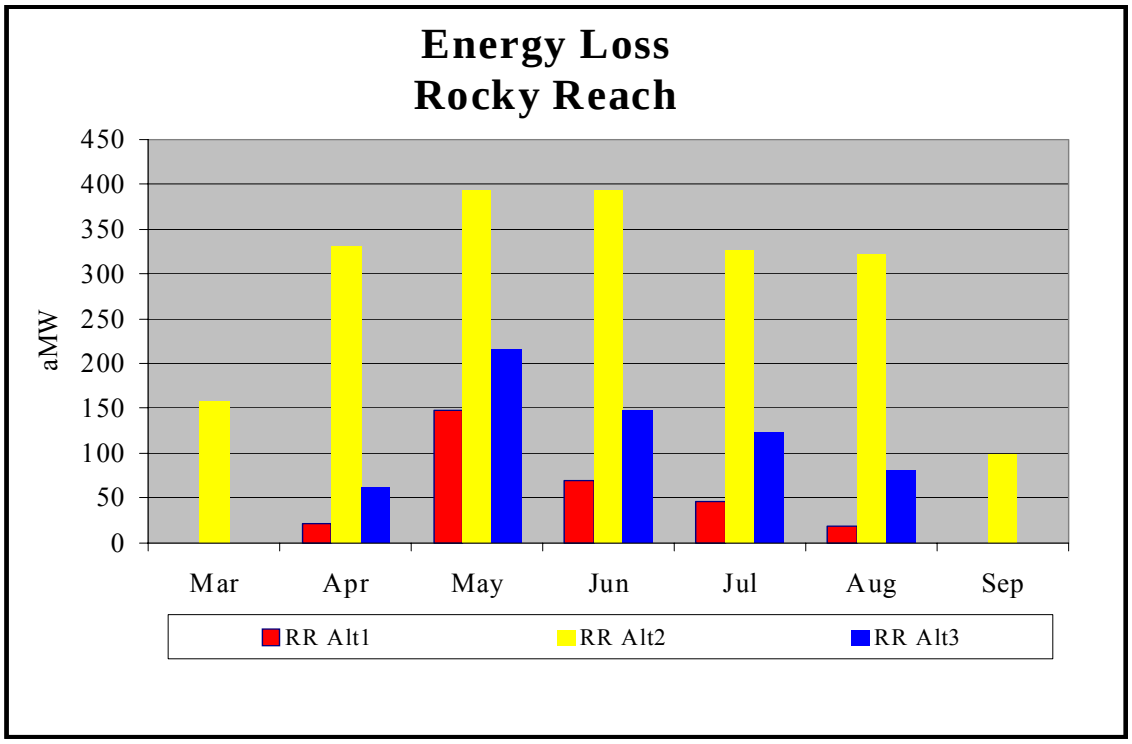

Figure F-11. Energy Loss on a Monthly Basis – Rocky Reach Project

By 2006, the energy due to spill for Alternative 3 decreases by 14 percent in May, 50 percent in June, and 33 percent for July to September. Given the forecasted relatively flat spill characteristics throughout the day, lost capacity is approximately equal to the lost energy in aMWs. For example, it would require 100 megawatts of capacity generating 100 percent of the time to generate a block of energy of 100 aMW. The average spill for Alternative 2 for Wells, Rocky Reach, and Rock Island represents a 40 percent spill from March 15 through September 15.

Biological Opinions Supporting Incidental Take Permits

Biological Opinion for Permit No. 1395 (2003)

National Marine Fisheries Service Endangered Species Act (ESA)
Section 7 Consultation Biological Opinion and Magnuson-Stevens Act
Essential Fish Habitat Consultation

Action Agencies: National Marine Fisheries Service (NMFS)
U.S. Fish and Wildlife Service (USFWS)
U.S. Bureau of Reclamation (BOR)

Species/Evolutionarily Significant Units (ESUs) Affected: Upper Columbia River (UCR) Steelhead (*Oncorhynchus mykiss*)
UCR Spring Chinook Salmon (*O. tshawytscha*)

Essential Fish Habitat Affected: Chinook Salmon

Activities Considered:
1. Issuance of Permit 1395 jointly to the Washington Department of Fish and Wildlife (WDFW), the Public Utility District No. 1 of Chelan County (Chelan PUD), and the Public Utility District No. 1 of Douglas County (Douglas PUD)
2. Issuance of Permit 1396 to the USFWS
3. Issuance of Permit 1412 to the Confederated Tribes of the Colville Reservation (Colville Tribes)

Consultation Conducted By: Salmon Recovery Division (SRD), Northwest Region
Consultation Number 2002/000981

This Biological Opinion (Opinion) constitutes NMFS' review of three section 10(a)(1)(A) permit actions that may affect UCR steelhead and UCR spring chinook salmon. It has been prepared in accordance with section 7 of the ESA of 1973, as amended (16 U.S.C. 1531 et seq.). It is based on information provided in the applications for the proposed permits, published and unpublished scientific information on the biology and ecology of endangered steelhead in the action area, and other sources of information. A complete administrative record of this consultation is on file with the SRD in Portland, Oregon.

1. CONSULTATION HISTORY

This Biological Opinion (Opinion) constitutes the review of NOAA's National Marine Fisheries Service (NMFS) proposed approval of three Endangered Species Act (ESA) section 10(a)(1)(A) permits for artificial propagation programs for the enhancement of upper Columbia River (UCR) steelhead.

On June 12, 2002, NMFS received an application for a new ESA section 10(a)(1)(A) permit from the Washington Department of Fish and Wildlife (WDFW) (WDFW 2002). This application requested authorization for annual take of endangered UCR steelhead and UCR spring chinook salmon associated with artificial propagation research and enhancement programs of steelhead in the UCR basin. Notice of the receipt of this permit application was published in the Federal Register on August 1, 2002 (67 FR 49906), and a public informational meeting was held on August 28, 2002, in Wenatchee, Washington to inform the public of the receipt of this permit application. This new permit 1395 is to replace the expired permit 1094.

Permit 1094 was issued to the WDFW on February 4, 1998 to carry out artificial propagation programs intended to enhance and conduct research on listed UCR steelhead (63 FR 8435). Following issuance, three modifications to permit 1094 were considered and enacted. Modification 1 includes authorization of incidental take of spring chinook salmon, additional measures to enhance WDFW's ability to manage adult returns, and a one-time-only increase in authorized hatchery releases effective in 1999 (March 25, 1999; 64 FR 14431). The WDFW requested modification 2 for take of ESA-listed species associated with a radiotelemetry study – this modification was addressed as Modification 3 of research permit 1114 (July 25, 2001; 66 FR 38641). The WDFW requested modification 3 for an increase in take of listed steelhead as part of a study of potential hatchery-origin fish survival benefits at Wells Hatchery (May 13, 1999; 64 FR 25873). Permit 1094 expired on May 31, 2003. The proposed permit 1395 would replace permit 1094.

In April 2002, negotiations on three Habitat Conservation Plans (HCPs) were concluded; *Anadromous Fish Agreement and Habitat Conservation Plan Wells Hydroelectric Project FERC[1] License No. 2149* with the Public Utility District No. 1 of Douglas County (Douglas PUD) for the operation of Wells Dam (DPUD 2002), and *Anadromous Fish Agreement and Habitat Conservation Plan Rocky Reach Hydroelectric Project FERC License No. 2145* (CPUD 2002a) with the Public Utility District No. 1 of Chelan County (Chelan PUD) for the operation of Rocky Reach Dam, and *Anadromous Fish Agreement and Habitat Conservation Plan Rock Island Hydroelectric Project FERC License No. 943* with Chelan PUD for the operation of Rock Island Dam (CPUD 2002b). These HCPs[2] are long term agreements that at the time of this

---

[2] *Each HCP agreement is subject to a separate Biological Opinion. This Opinion addresses the artificial propagation of UCR steelhead required in each HCP. Separate Biological Opinions also address artificial*

Opinion, have as signatories to each agreement NMFS, the PUDs, the WDFW, the U.S. Fish and Wildlife Service (USFWS), and the Confederated Tribes of the Colville Reservation (Colville Tribes). They provide the PUDs with some degree of certainty for the long-term operation of these projects and require the PUDs to provide mitigation in the form of a tributary fund for habitat improvement projects, and artificial propagation programs to mitigate for unavoidable loss of natural fish production due to habitat inundation and passage mortality at the projects. The HCPs were developed to protect five species of anadromous salmonids, including endangered UCR steelhead. The HCP related UCR steelhead programs would be intended as a conservation measure to ensure the persistence of the species. The HCP agreements restrict the PUDs and NMFS from changing the artificial propagation production levels during the period of this permit. The HCPs require Hatchery Committees[3] that may adjust the operation or implementation strategy of the programs based on new scientific data, changes in NMFS hatchery policy, or recommendations of the HCP Hatchery Committees.

Additionally, on June 11, 2002, NMFS received an application for a ESA section 10(a)(1)(A) permit from the USFWS (USFWS 2002), requesting multi-year authorization for annual take of UCR summer steelhead and UCR spring chinook salmon associated with UCR steelhead artificial propagation research and enhancement program. Notice of the receipt of this permit application was published in the Federal Register on August 1, 2002 (67 FR 49906), and a public informational meeting was held on August 28, 2002, in Wenatchee, Washington to inform the public of the receipt of this permit application. The USFWS was previously authorized to carry out an UCR steelhead enhancement program under permit 1118 which expired on May 31, 2003. The proposed permit 1396 would replace the expired permit 1118.

Thirdly, on October 29, 2002, NMFS received an application for ESA a section 10(a)(1)(A) permit from the Colville Tribes (CCT 2002), requesting multi-year authorization for annual take of UCR summer steelhead and UCR spring chinook salmon associated with UCR steelhead artificial propagation research and enhancement program. Notice of the receipt of this permit application was published in the Federal Register on January 14, 2003 (68 FR 1826). The Colville Tribes permit 1412 UCR steelhead artificial propagation program is a newly proposed research and enhancement program and has not been considered under previous ESA permitting actions.

NMFS has proposed and evaluated the action of issuing incidental take statements (ITSs) in relation to the National Environmental Policy Act (NEPA) for the three HCPs as its preferred alternative in the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (FEIS) (NOAA Fisheries 2002). An Environmental Assessment (EA) was prepared and

---

propagation programs of other anadromous fish species.

[3] *Each HCP agreement specifies the formation of a Hatchery Committee which consists of one representative of each signatory entity to the specific HCP. In general the HCP Hatchery Committee representation is likely to be similar for all three HCPs.*

opened for public comment on April 17, 2003 (68 FR 18952) which assessed the potential impacts of the issuing permits 1395, 1396, and 1412 on the environment. A finding of no significant impact (FONSI) was signed on July 10, 2003, following consideration and incorporation of public comments received on the EA (NMFS 2003).

NMFS is initiating a new consultation with itself on approval of these three section 10(a)(1)(A) permits for research and enhancement programs in the UCR summer steelhead evolutionarily significant unit (ESU). The Salmon Recovery Division decided to group these action together in a single consultation pursuant to 50 CFR §402.14(c) because they are similar in nature and will affect the same listed species. This Opinion will consider the impacts of these UCR steelhead artificial propagation enhancement programs in the Methow, Okanogan, and Wenatchee basins on anadromous salmonid species listed under the ESA.

An early product of HCP negotiations was the *Biological Assessment and Management Plan* (BAMP) (1998) developed by technical representatives from the co-managers[4] and signatory entities of the HCPs. The BAMP included review and recommendation for all artificial propagation programs in the UCR basin, HCP related and otherwise. Although the BAMP does not create legal obligations as a stand-alone document, it does provide guidance for program management and monitoring and evaluation of UCR artificial propagation programs. The HCPs define the commitment by the PUDs for implementation of hatchery propagation programs for steelhead, summer/fall chinook salmon, spring chinook salmon and sockeye salmon for the middle and UCR region. The proposed actions addressed in this Opinion are derived from the HCP agreements, the WDFW permit application, the USFWS permit application, and the Colville Tribes permit application, which together constitute a comprehensive plan for steelhead artificial propagation in the UCR basin.

In developing this Opinion, NMFS considered the information presented in the documents mentioned above, including the three HCPs; the Biological Opinion on 1995 to 1998 Hatchery Operations in the Columbia River Basin (NMFS 1995); information in the NMFS report, *Pacific Salmon and Artificial Propagation Under the Endangered Species Act* (Hard *et al.* 1992); the *Biological Opinion on Effects on Upper Columbia River Spring Chinook Salmon Supplementation Program and Associated Scientific Research and Monitoring Conducted by the Washington Department of Fish and Wildlife and the U.S. Fish and Wildlife Service* (NMFS 2002a), information provided in reports requires by previous permits; and information from the best scientific and commercial data available.

[4] *Anadromous fisheries resource co-managers in the UCR basin include the WDFW, the USFWS, NMFS, the Colville Tribes, and the Yakama Nation.*

1.1 Analysis Framework

Over the course of the last decade and hundreds of ESA section 7 consultations, NMFS developed the following approach for applying the ESA Section 7(a)(2) standards as defined by 50 CRF §402.02 when determining what effect a proposed action is likely to have on a given listed species. In conducting analyses of the actions under Section 7 of the ESA, NMFS uses the following steps:

1. Define the biological requirements and current status of each listed species and the relevance of the environmental baseline to the species' current status in the action area (Section 3).

2. Determine the effects of the proposed or continuing action on listed species and their habitat and evaluate any cumulative effects within the action area (Section 4).

3. Evaluate whether the effects of the proposed action, taken together with any cumulative effects and added to the environmental baseline, can be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of the affected species or is likely to destroy or adversely modify their designated critical habitat (Section 5).

2. PROPOSED ACTIONS

NMFS proposes to issue three section 10(a)(1)(A) enhancement permits: Permit 1395 jointly to the WDFW, the Chelan PUD, and the Douglas PUD for artificial propagation programs required under the HCP agreements; permit 1396 to the USFWS; and permit 1412 to the Colville Tribes. These permits would authorize direct take of endangered, naturally-produced and artificially propagated UCR steelhead and incidental take of UCR spring chinook salmon.

This Opinion considers artificial propagation activities which include the (1) biological sampling and release of adult UCR steelhead for annual run evaluation, (2) management of adult returns of UCR steelhead from artificial propagation programs, (3) collection, holding, and artificial spawning of adult UCR steelhead, (4) transfers of UCR steelhead eggs and/or juveniles to appropriate locations, (5) incubation and rearing of UCR steelhead fertilized eggs through the smolt stage, (6) release of propagated UCR steelhead juveniles into the UCR basin, and (7) monitoring and evaluation of the UCR steelhead artificial propagation program. Artificial propagation programs of UCR steelhead have been ongoing since the 1960's. Improvements, hatchery reform measures, and a focus on recovery of natural environment populations have occurred since the UCR steelhead ESU was listed under the ESA in August 1997. The location of the UCR steelhead ESU, the artificial propagation facilities, and the dam locations pertinent to this Opinion are presented in Figure 1. Terms and conditions that NMFS would include in each permit to ameliorate potential negative effects are listed below and additional permit specific terms and conditions follow the specific operating agency activities. These terms and conditions and proposed activities by each agency together constitute the proposed actions.

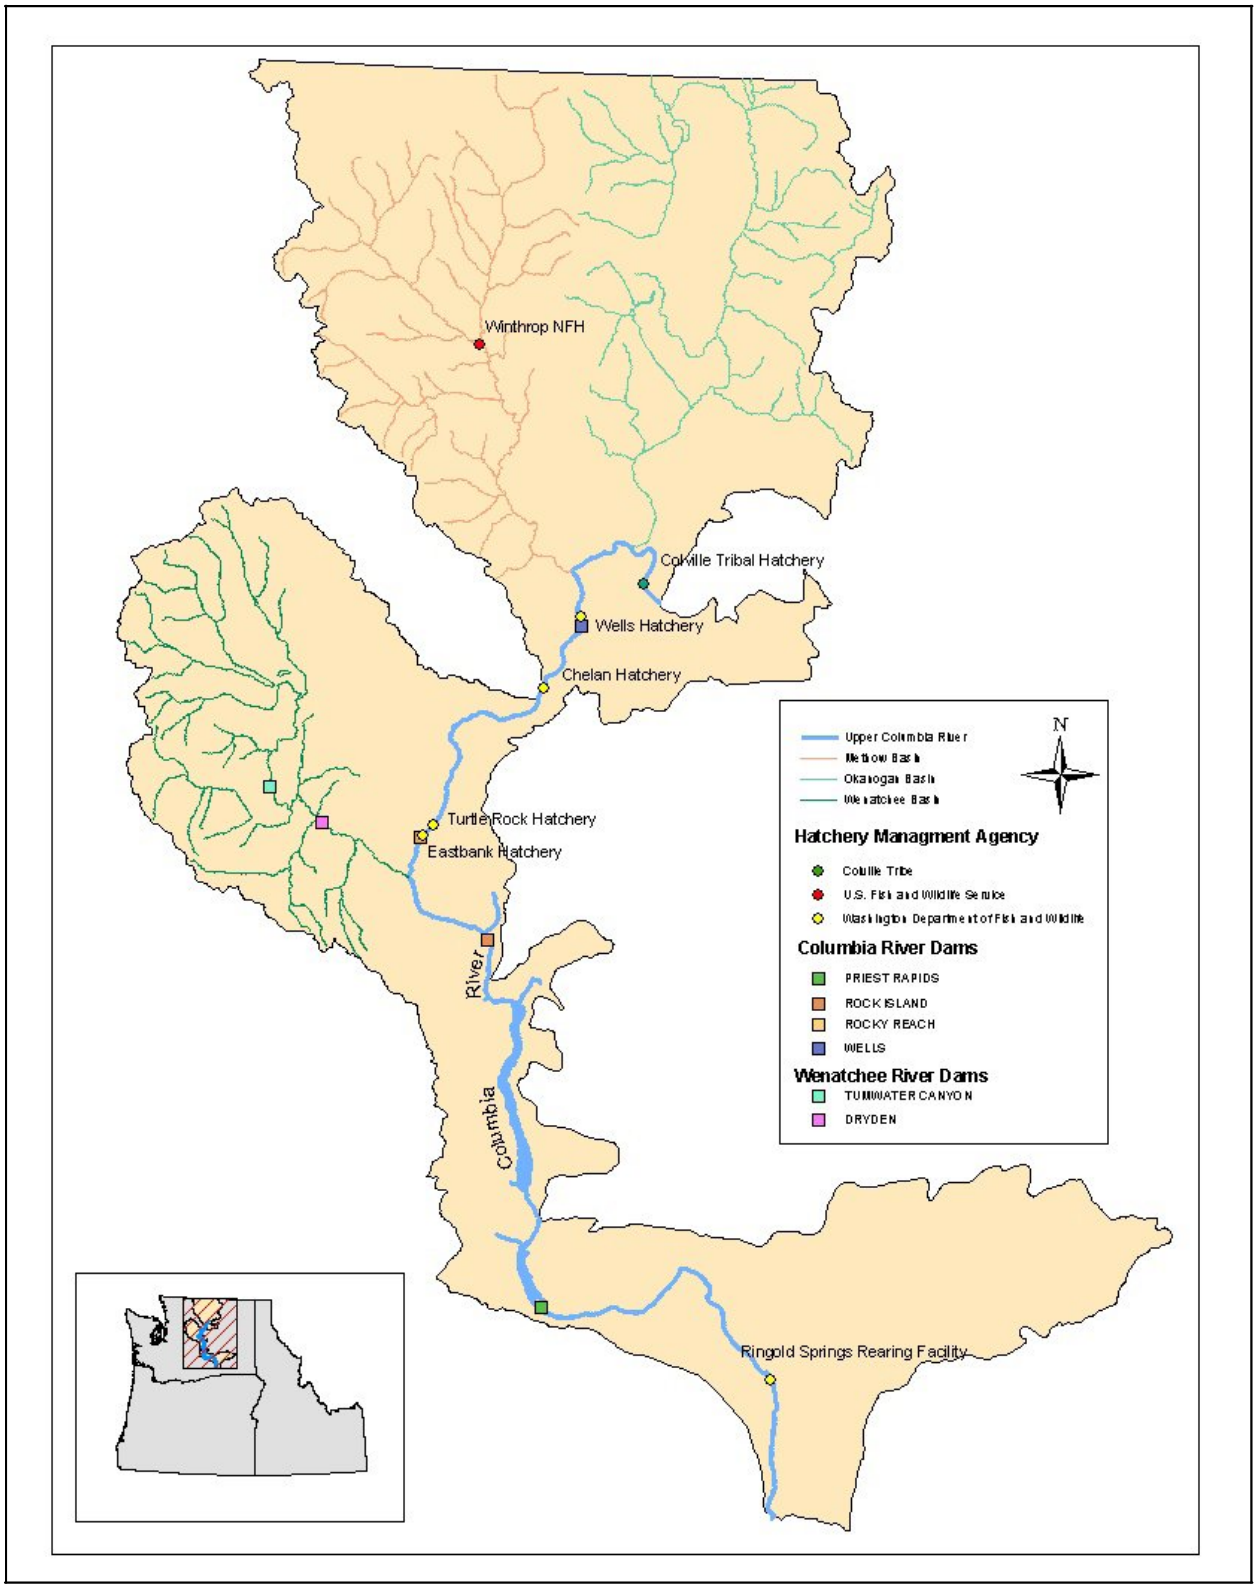

Figure 2. Map of the upper Columbia River steelhead ESU with hatchery facilities and dams relevant to the proposed artificial propagation programs identified.

2.1 General Conditions

The following conditions would be common to all three permits consulted upon in the Opinion. In all cases, the permit holder(s) must:

1. The permit holder(s) are responsible for the actions of any individual operating under the authority of this permit. Such actions include capturing, handling, releasing, transporting, maintaining, and caring for any ESA-listed species authorized to be taken by this permit.

2. The permit holder(s) must ensure that all ESA-listed species are handled carefully. Should NMFS determine that a procedure provided for under this permit is no longer acceptable, the Permit Holders must immediately cease such activity until an acceptable substitute procedure is identified and approved by NMFS.

3. Measures shall be applied to ensure that artificially propagated UCR steelhead juveniles released will be ready to actively migrate to the ocean. To meet this condition, fish must be released at a uniform size and state of smoltification that ensures that the fish will migrate seaward without delay after release. Variance from this smolts-only release requirement shall only be allowed in the event of an emergency, such as flooding, water loss to raceways, or vandalism, that necessitates early release of ESA-listed steelhead to prevent catastrophic mortality. Any emergency steelhead releases made by the action agencies shall be reported immediately to the NMFS Salmon Recovery Division in Portland.

4. The permit holder(s) must allow any NMFS employee or representative to accompany field personnel while they conduct authorized activities.

5. The permit holder(s) are responsible for obtaining all other federal, state, and local permits/authorizations needed for the proposed activities.

6. Each ESA-listed fish handled out-of-water for the purpose of recording biological information must be anesthetized. Anesthetized fish must be allowed to recover (e.g., in a recovery tank) before being released. Fish that are simply counted must remain in water but do not need to be anesthetized.

7. ESA-listed fish must be handled with extreme care and kept in water to the maximum extent possible during sampling and processing procedures. Adequate circulation and replenishment of water in holding units is required. When using methods that capture a mix of species, ESA-listed fish must be processed first. The transfer of ESA-listed fish must be conducted using equipment that holds water during transfer.

8. The permit holder(s) shall ensure that water intakes into artificial propagation facilities be properly screened in compliance with 1995 NMFS screening criteria and as per the 1996

addendum to those criteria (NMFS 1996). As an alternative, they shall comply with transitional criteria set forth by NMFS in 1999 for juvenile fish screens constructed prior to the establishment of the 1995 criteria (NMFS 1996), to minimize risks to listed salmon and steelhead. The permit holder(s) shall inspect and monitor the water intake screen structures at their hatchery facilities to determine if listed salmon and steelhead are being drawn into the facility; the results of this monitoring shall be included in annual reports.

9. The permit holder(s) shall implement the "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" (NWIFC and WDFW 1998) and Pacific Northwest Fish Health Protection Committee (PNFHPC 1989) guidelines to minimize the risk of fish disease amplification and transfer, and to ensure that artificially propagated fish would be released in good health.

10. The permit holder(s) shall conduct hatchery operations and monitor hatchery effluent in compliance with applicable National Pollutant Discharge Elimination System (NPDES) (EPA 1999) permit limitations.

11. In the event that circumstances, such as unanticipated, higher-than-expected fecundity, or high egg-to-fry survival rates, lead to the inadvertent possession of steelhead substantially in excess (>110 %) of program production levels specified above, then surplus eggs or fish shall be culled from the population in a manner consistent with achieving program goals.

12. Visual observation protocols must be used instead of intrusive sampling methods whenever possible. This is especially appropriate when merely ascertaining the presence of anadromous fish.

13. The permit holder(s) are responsible for any biological samples collected from listed species, which shall only occur if they are valuable for research purposes. The permit holder(s) may not transfer biological samples to anyone not listed in the application without prior written approval from NMFS.

14. The permit holder(s) must coordinate with other co-managers and researchers to ensure that no unnecessary duplication and/or adverse cumulative effects occur as a result of the permit holder's activities.

15. All artificially propagated UCR steelhead juveniles shall be externally marked (i.e., visual implant elastomer tag or adipose fin clipped) prior to release.

Reports and Annual Authorization

NMFS contact for all reports: NMFS - Salmon Recovery Division
525 NE Oregon Street, Suite 510
Portland, Oregon 97232
Phone: (503) 230-5407
Fax: (503) 872-2737

16. The permit holder(s) must notify NMFS as soon as possible, but no later than two days after, any authorized level of take is exceeded or if such an event is likely. The permit holder(s) must submit a written report detailing why the authorized take level was exceeded or is likely to be exceeded.

17. The permit holder(s) shall update and provide to NMFS by December 15th of each year, the projected hatchery releases by age class and location for the coming year.

18. The permit holder(s) shall provide annual reports that summarize numbers, pounds, dates, tag/mark information, locations of artificially propagated fish releases, and monitoring and evaluation activities that occur within the hatchery environment, and adult return numbers to the UCR basin for each program. The permit holder(s) shall ensure collection and reporting of the coefficient of variation around the average (target) steelhead release size immediately prior to their liberation from the acclimation sites as an indicator of population size uniformity and smoltification status. Reports shall also include any preliminary analyses of scientific research data, any problems that may have arisen during conduct of the authorized activities, a statement as to whether or not the activities had any unforeseen effects, and steps that have been and will be taken to coordinate the research or monitoring with that of other researchers. Unless otherwise noted in the specific terms and conditions, the reports shall be submitted by January 31st, of the year following release (i.e., brood year 2002, release year 2003, report due January 2004) to NMFS.

19. The permit holder(s) must provide plans for future projects and/or changes in sampling locations or enhancement/research protocols and obtain approval from NMFS prior to implementation of such changes.

Penalties and Sanctions

20. The persons actually doing the activity must have a copy of this permit while conducting the authorized activities.

21. The permit holder(s) may not transfer or assign this permit to any other person as defined in Section 3(12) of the ESA. This permit ceases to be in effect if transferred or assigned to any other person without NMFS' authorization.

22. If a permit holder violates any permit term or condition, they will be subject to any and all penalties provided by the ESA.

23. The permit holder(s), in effectuating the take authorized by this Permit, are considered to have accepted the terms and conditions of this permit and must be prepared to comply with the provisions of this permit, the applicable regulations, and the ESA.

24. The Salmon Recovery Division, NMFS, may amend the provisions of this permit after reasonable notice to the permit holder.

25. 50 CFR Section 222.23(d)(8) allows NMFS to charge a reasonable fee to cover the costs of issuing permits under the ESA. The fee for this permit has been waived.

26. Any falsification of annual reports or records pertaining to this permit is a violation of this permit.

27. Under the terms of the regulations, a violation of any of the terms and conditions of this permit will subject the permit holder(s), and/or any individual who is operating under the authority of this permit, to penalties as provided for in the ESA.

2.2 Permit 1395

NMFS proposes to issue permit 1395 jointly to the WDFW, the Chelan PUD, and the Douglas PUD. The activities undertaken by each of these entities varies based on their permit applications, program operational roles, and resource management responsibilities. The WDFW is generally the lead co-manager of the fisheries resources of the state of Washington and is also the operator of the hatchery facilities at which the proposed activities would occur. The activities proposed by WDFW include adult return monitoring, management of returning hatchery-origin steelhead adults, general hatchery operations associated with the UCR steelhead enhancement programs. Responsibility for research, and monitoring and evaluation of the UCR steelhead artificial propagation program activities overlap between the WDFW and the PUDs. At this time, monitoring and evaluation, and research activities are proposed to be conducted by the WDFW, however, in the future, some monitoring and research activities may be funded by the PUDs and conducted by other entities as described in the three HCP agreements. The PUDs propose to provide funding and implementation support for the WDFW managed programs. A description of activities proposed by each applicant is provided below, followed by the additional terms and conditions that would be included in the permit. Permit 1395 would replace permit 1094 which expired in May 2003.

2.2.1 WDFW Proposed Activities

The WDFW proposes to collect annual run composition data, manage the resultant artificial propagation adult UCR steelhead returning to the middle and UCR basin, operate UCR steelhead artificial propagation programs in hatchery facilities, and conduct research, monitoring, and evaluations relating to artificially propagated steelhead in the UCR basin. Reports will be submitted to NMFS annually to summarize all activities associated with each element described below.

2.2.1.1 Adult Steelhead Stock Assessment

The WDFW proposes to collect, anesthetize, biologically sample, and return to the river adult listed UCR steelhead in the east ladder of the Priest Rapids Dam on the Columbia River at river mile (rm) 397. Sampling would occur 16 to 32 hours per week during the migration period in order to achieve a minimum sample rate equal to 10 percent of the run. The purpose of this sampling is to (1) determine upriver population size, (2) estimate hatchery to natural (wild) fish ratios, (3) determine age class contribution, and (4) evaluate the need for managing returning hatchery steelhead consistent with ESA recovery objectives which include fully seeding spawning habitat with naturally produced UCR steelhead supplemented with artificially propagated enhancement steelhead. The WDFW also proposes to externally tag adipose fin-clipped sampled steelhead at Priest Rapids Dam after September 9th as a means to exclude them from harvest in years when fisheries would be allowed in areas above the dam. In some years, up to 400 of the steelhead sampled at Priest Rapids Dam would be radio-tagged or tagged with some other active-transmitting tag to investigate dam passage, migration, and spawning characteristics.

To minimize potential adverse effects on listed UCR steelhead, the following measures will be used and defined in the permit as terms and conditions by NMFS:

- No more than six fish will be in the trap box at one time;
- Fish will be removed from the trap as quickly as possible;
- Steelhead will be processed first;
- Nets will be 1-inch soft nylon mesh;
- Stock solution of 500 grams tricaine methanesulfonate (MS-222) powder to 2.5 gallons of water will be used to achieve proper anesthesia;
- Temperature and dissolved oxygen in the anesthetic bath will be monitored continuously;
- Anesthetic bath will be changed when the bath warms 2°C above river water temperature.
- Trap operations will cease if river water temperature exceeds 21°C (69.8°F).

2.2.1.2 Management of Returning Adult Hatchery Steelhead

These programs would be intended to enhance the naturally reproducing UCR steelhead populations in the UCR region. The number of natural origin and artificially propagated UCR steelhead that return to the UCR region is influenced by a variety of factors including the number of artificially propagated UCR steelhead released and the environmental conditions they experience after release, such as during their downstream migration out of tributaries and the Columbia River and conditions in the ocean environment. The uncertainty of those conditions can result in years of low returns of UCR steelhead, both naturally and artificially propagated or in high returns. The WDFW has identified several tools for managing returning adult UCR steelhead particularly in high return years. These tools include harvest fisheries directed on externally identifiable artificially propagated UCR steelhead and removal of artificially propagated UCR steelhead at dam ladders and other fish trap sites. The WDFW identifies harvest fisheries as the preferred tool to manage artificially propagated adult UCR steelhead. Furthermore, the WDFW separates harvest activities into reaches below Priest Rapids Dam and reaches above Priest Rapids Dam.

Below Priest Rapids Dam: The WDFW proposes to open a recreational harvest fishery below Priest Rapids Dam (in the vicinity of Ringold Springs Rearing Facility) for hatchery steelhead when the run size above Priest Rapid Dam is sufficient to meet interim abundance targets, which based on current information requires at least 8,300 steelhead at Priest Rapids Dam (WDFW 2002). The area encompasses waters below Priest Rapids Dam in the downstream portion of the Hanford Reach from the Highway 395 bridge at Pasco to the old Hanford town site power line towers, a distance of 32 miles. In the proposed fishery, anglers may retain adipose fin-clipped and/or adipose fin-clipped plus ventral fin-clipped steelhead. All unmarked steelhead must be released. The dates for the proposed fishery vary according to fishing method. Anglers may fish from the bank in addition to floating devices from September 16th through March 31st. From April 1st through June 15th anglers may only fish from the bank at the Ringold Springs site and all floatation devices would be prohibited. Bait would be allowed throughout the fishing period. The starting date for the fishery may be postponed until October 15th if pre-season or in-season evaluation of the steelhead run indicates that the migration over Priest Rapids Dam is delayed or below levels needed to meet recovery objectives. Additionally, the WDFW proposes to remove hatchery steelhead captured in the Ringold Springs ladder that would be in excess of broodstock and recovery needs. These fish would be transported and released in landlocked ponds and lakes to provide additional harvest opportunities on the excess hatchery steelhead.

Above Priest Rapids Dam: The WDFW propose to manage the number of artificially propagated adult steelhead on the spawning grounds in the Wenatchee, Methow, and Okanogan basins. On an annual basis, the run composition information gathered through sampling conducted at Priest Rapids Dam (described above in Section 2.2.1.1) will be assessed on or shortly after September 15th. The components of the run (naturally produced steelhead, adipose fin-clipped hatchery steelhead, and adipose fin-present hatchery steelhead) will be considered in decided whether or not removal of adipose fin-clipped steelhead is warranted.

If the natural component of the run is predicted to be below 1,300 steelhead, no steelhead fishery would be proposed, regardless of total run size. If the natural component is expected to exceed 1,300 steelhead and the total run size is predicted to exceed 9,550, then the WDFW proposes to open a recreational fishery. The fishery would be open from about October 1st through about March 31st, by emergency rules. Excess adipose fin-clipped steelhead may also be removed at the Wells Dam and Wells Hatchery for placement in local lakes or ponds for recreational angling opportunity.

The specific locations and retention limits of recreational harvest opportunity would be determined based on the results of a fishery model designed to estimate the effects of removing adipose fin-clipped steelhead from the population. The model considers the following elements; total steelhead run size, percentage of natural origin steelhead, percentage of adipose present artificially propagated steelhead, the percentage of adipose fin-clipped steelhead, and the effects of hooking mortality. Mark and tag identification at Priest Rapids Dam combined with known artificially propagated juvenile release group information would result in estimates of the number of steelhead returning to each tributary basin. The model would then be run using the calculated run estimates for each tributary basin (Okanogan, Methow, and Wenatchee).

If a fishery directed on surplus hatchery produced steelhead is authorized, the gear regulations would allow the use of bait in the mainstem Columbia River above Priest Rapids Dam. Any proposed tributary basin (Methow, Okanogan, and Wenatchee) fisheries would open under "selective gear rules," which are defined as follows: Only unscented artificial flies or lures with one barbless single hook, bait is prohibited; fish may be released until the daily limit is retained; If any fish has swallowed the hook or is hooked in the gill, eye, or tongue, it should be kept if legal to do so. Regulations requiring the release of adipose-present steelhead would be in place on all waters. Regulations may also limit the retention of steelhead with any external tags that may be associated with the Priest Rapids sampling project or other studies in the basin.

2.2.1.3 Artificial Propagation Program

The WDFW proposes to enhance the UCR steelhead ESU using artificial propagation techniques that include the collection of broodstock, spawning of adults, incubation of eggs, rearing, acclimation, and release of juvenile steelhead. A general description of the programs is provided here; for additional detail, please see the permit application (WDFW 2002). The WDFW proposes to collect, hold, and spawn adult steelhead broodstock and incubate, rear, and release the progeny of the broodstock in various hatchery facilities. The current yearling steelhead smolt release goals, general release area, and stock are provided in Table 1.

Table 1. Yearling smolt release targets for WDFW operated artificial propagation programs of UCR steelhead by general release area and broodstock collection location.

Release Area	Smolt Production Target	Broodstock Collection
Above Wells Dam (Methow and Okanogan River basins)	349,000	Wells Dam
Wenatchee River basin	400,000	Wenatchee River
Below Priest Rapids Dam (Ringold Springs area of Columbia River)	180,000	Wells Dam

Broodstock collection is proposed at: (1) Wells Dam (rm 516) and Wells Hatchery on the Columbia River, and (2) Dryden (rm 16) and Tumwater (rm 33) Dams on the Wenatchee River. Future broodstock collections would be proposed for the Methow and Okanogan Rivers, however no locations or facilities have been identified yet. The WDFW proposes to develop annual broodstock collection and spawning protocols in coordination with NMFS, and the HCP Hatchery Committees to allow for consideration of annual variation in run sizes, ages, and origins (natural and hatchery). Further details for each collection facility are provided in the WDFW application.

Broodstock collection protocols will include limits on the number of days and hours of trap operation. Specific handling procedures and reporting requirements will also be defined. In general, broodstock collection activities would occur with the following sideboards:

- Broodstock would be collected throughout the duration of the run;
- Traps would be checked and all fish removed at least daily;
- Trapping at Wells Dam would occur no more that 3 days a week, if both east and west ladder traps are utilized they would operate concurrently not to exceed 16 hours per day;
- Up to 373 steelhead would be collected at Wells Dam;
- Up to 123 or 33 percent, whichever is lower, of the broodstock could be natural origin steelhead;
- Passive trapping in the Wenatchee River at Dryden Dam would occur 24 hours a day at both the left and right bank traps;
- Trapping at Tumwater Dam would generally be limited to three days per week and 16 hours per day if actively operated;
- Hook and line collection of steelhead broodstock would be utilized as a last resort and only if traps were not effective;
- Up to 208 steelhead would be collected from the Wenatchee River;
- Up to 50 percent of the broodstock would be natural origin steelhead.

Following collection, the WDFW proposes to hold, humanely kill, and manually spawn steelhead at Wells and Eastbank Hatcheries. The Wells program will maximize matings of hatchery to natural origin steelhead. The Wenatchee program at Eastbank Hatchery will initially maximize the contribution of natural origin (wild) steelhead in creating rearing crosses of hatchery to natural (H × W) and natural to natural (W × W) matings for comparison and evaluation to hatchery to hatchery (H × H) mating progeny. Based on mating studies results, adjustments in spawning protocols may be made to improve program efficacy.

The WDFW proposes to initially incubate steelhead eggs at Wells and Eastbank Hatcheries. Up to 125,000 eyed eggs may be transferred from Wells Hatchery to Winthrop National Fish Hatchery (NFH) for continued incubation, rearing and eventual release (see Section 2.3 below). Wells Hatchery proposes to transfer up to 240,000 eyed eggs for the Ringold Springs program to other WDFW facilities for incubation and early rearing. These eggs will be from the earliest spawn dates. Eastbank Hatchery may transfer eyed eggs to Chelan Hatchery for incubation and early rearing to achieve specific rearing strategy goals of producing the highest quality smolts.

Juvenile rearing would occur at Wells Hatchery for fish destined for release in the Methow and Okanogan basins. Juvenile rearing would occur at Eastbank, Turtle Rock, and Chelan Hatcheries for fish destined for release in the Wenatchee River basin. Juvenile steelhead will be externally marked (e.g., adipose fin clipped) or tagged (e.g., visual elastomer tag) prior to release and at least a portion of the annual release will be internally tagged with a coded-wire tag (CWT) or passive integrated transponder (PIT) tagged prior to release.

Wells Hatchery proposes to release 349,000 smolts per year as specified in the HCP agreement with Douglas PUD, of which, 300,000 would be production to compensate for habitat loss due to inundation from Wells Dam pool. Smolts that volitionally migrate to a collection raceway downstream of the rearing ponds will be collected and directly scatter planted into the Methow and Okanogan basins. Juveniles that do not voluntarily exit the pond will be forced into the collection area for direct stream release in lower river areas because these fish may have a higher tendency to residualize. Final rearing and acclimation may occur in the Methow or Okanogan basin for some release groups, in some years, if appropriate sites are identified and available. No sites have been identified for acclimation at the time the application was received. The annual allocation of smolts released into the Methow and Okanogan Rivers would be determined by the HCP Hatchery Committees.

Releases into the Wenatchee River basin are proposed at 400,000 smolts as specified in the two HCP agreements with Chelan PUD. Releases would occur as direct stream plants, volitional release from Chiwawa Ponds, or potentially other acclimation sites in the Wenatchee basin which have not yet been developed. Release from Ringold Springs proposed at 180,000 smolts annually into the Columbia River as funded by the Mitchell Act.

The WDFW proposes to implement the following measures into the artificial propagation program operation to minimize potential negative impacts on ESA-listed species:

- Conduct routine water monitoring to ensure that the levels of total suspended solids, settleable solids, and water temperature at each facility to remain compliant with NPDES permits issued by Washington Department of Ecology;
- Follow fish disease control guidelines developed by IHOT (1995) and the PNFHPC (1989) to reduce the incidence of fish diseases;
- Conduct routine, generally monthly, fish growth monitoring during rearing at each facility;
- Dispose of juvenile and adult carcasses via the local solid waste management system, on-station burial, or distributing carcasses into the river system of origin for nutrient enhancement after appropriate fish health certification.

2.2.1.4 Research, Monitoring, and Evaluation Activities

Research, monitoring, and evaluation plans will be developed by the HCP Hatchery Committees as described in Section 2.2.2 (Chelan PUD and Douglas PUD Proposed Activities). Additional details of the monitoring and evaluation plan development time lines and responsibilities are provided in the three HCP agreements. Tasks proposed for consideration at this time, which will be included in the plans developed by the HCP Hatchery Committees, include monitoring within the hatchery facilities and monitoring of artificially propagated steelhead in the natural environment.

2.2.1.4.1 Within-Hatchery Environment Monitoring

Monitoring and evaluation activities will be conducted on all of the steelhead life stages that occur within the hatchery facility environment. The HCP Hatchery Committees are expected to fine-tune the evaluation activities through time to improve the knowledge base and success of the artificial propagation programs. The following tasks would be required as part of the monitoring plans:

Juvenile Steelhead

Growth rate and general health will be monitored monthly.

Green egg-to-eyed egg, eyed egg-to-fry, and fry-to-smolt survival rates will be determined.

Numbers, size, and health condition of all steelhead juveniles will be determined prior to or at the time of any transfers among facilities, and prior to release.

Adult Steelhead

Broodstock (and mortalities at trap locations) would be sampled for stock composition analysis including determination of sex, age, and stray rates.
Biological sampling may include meristic, morphometric, tissue samples (for genetic stock identification or DNA (deoxyribonucleic acid) analysis), and scale sampling.
Snouts of CWT steelhead would be collected.
Annual determination of average fecundity will be conducted for a representative sample of spawned females in each program using an electronic egg counter.

2.2.1.4.2 Natural Environment Monitoring

Natural environment monitoring of juvenile artificially propagated steelhead is proposed to be conducted using a variety of standard techniques such as angling, trapping, snorkeling. In general, these population sampling techniques would be used to identify both external marks and tags and internal tags. Residualism of hatchery reared steelhead in the Wenatchee and Methow rivers will be evaluated by sampling of the resident river population during August using standard angling techniques. Migration characteristics and tributary productivity would be monitored using juvenile fish traps. Traps are proposed to be operated in the Chiwawa River, the upper and lower Wenatchee River, the Twisp River, and the Methow River. These traps would form a comprehensive juvenile monitoring program investigating the productivity of artificially propagated and natural origin UCR steelhead in the tributary environment. The trapping efficiency would be expected to vary from below four percent up to 30 percent depending on tributary conditions such as discharge and debris load. The capture of artificially propagated UCR steelhead in the juvenile traps would also vary based on release location in relation to trap site and method of release. For example UCR steelhead smolts released volitionally over a period of four to six weeks may be captured at a higher rate overall compared to a direct stream release at a single point in time. In the case of the latter release, the traps would not be operated as the large pulse of artificially propagated UCR steelhead migrate past the trap site. In the former situation, a relatively small number of released fish could be captured daily throughout the volitional release period.

Monitoring of adults in the natural environment that is additional to the Priest Rapids Dam sampling previously described in Section 2.2.1.1 (Adult Steelhead Stock Assessment), will include collection of biological data, such as scale samples and CWT recoveries, in fisheries, at trap sites, spawning ground surveys, and in carcass surveys. Spawning and carcass surveys are proposed to be conducted by WDFW staff in coordination with PUD, Tribal, USFWS, and U.S. Forest Service personnel. Surveys would be done on foot, from an airplane, or from a boat, depending on survey area.

The WDFW proposes to develop a study to assess the relative reproductive success between hatchery-reared and naturally produced steelhead using DNA micro-satellite technology. This study will provide valuable information concerning the effectiveness of the artificial propagation programs in contributing to the recovery of UCR steelhead. The study design will be subject to approval by the HCP Hatchery Committee as described in the Chelan PUD HCPs (CPUD 2002a, 2002b). The preliminary study design proposes to allow up to 120 adult steelhead, of which no more than 60 would be of natural origin, to spawn in a controlled waterway, potentially the Wells Hatchery spawning channel. Progeny of these steelhead would be sampled for DNA analysis and a portion would be PIT tagged and subsequently released into their parental origin river. Migrating smolts would be identified by the PIT tag code at downstream locations. As study fish return to the region and would be identified (via the PIT tags), comparison to the previous sample groups would be conducted.

2.2.2 Chelan PUD and Douglas PUD Proposed Activities

The Chelan PUD and the Douglas PUD propose to provide the funding and implementation support for UCR steelhead as provided by the HCPs (CPUD 2002a, 2002b; DPUD 2002). Please see the three HCP agreements for additional details of their proposed actions and obligations which would be incorporated by reference into permit 1395.

The PUDs propose to implement the specific elements of the steelhead programs consistent with overall objectives of rebuilding natural populations and compensating for unavoidable inundation and project mortality that results from the operation of Rock Island, Rocky Reach, and Wells Dams. Implementation includes fully funding the hatchery facilities, operations and evaluations of the artificial propagation programs. Program objectives will be developed by the Joint Fisheries Parties[5] (JFP) and include contributing to the rebuilding and recovery of naturally reproducing populations of UCR steelhead in their native habitats, while maintaining genetic and ecologic integrity, and supporting harvest. Specific actions needed to implement the artificial propagation programs may be altered and modifications to program implementation may be made through the HCP Hatchery Committees as described in the HCPs (CPUD 2002a; 2002b; DPUD 2002).

The PUDs or their designated agents propose to operate the hatchery facilities according to the terms of Section 8 "Hatchery Compensation Plan" of the HCPs, the ESA section 7 and 10 permit(s), and in consultation with the HCP Hatchery Committees. The total number of artificially propagated steelhead that Chelan PUD and Douglas PUD would provide funding is initially set at 400,000 smolts for Chelan PUD and 349,000 for Douglas PUD. An annual increase of up 150,000 steelhead smolts could be proposed in some years if needed to conduct survival studies at Rock Island, Rocky Reach or Wells dams. This production level increase

[5] *For the purposes of this Opinion the Joint Fisheries Parties are the co-manager agencies who have signed the three HCP agreements. At the time of developing this Opinion they include NMFS, the WDFW, the USFWS and the Colville Tribes.*

would require the collection of about 55 adult steelhead broodstock. The production increase and the survival study design must be recommended and approved by the HCP Hatchery Committees and the HCP Coordinating Committees prior to retention of UCR steelhead. Outside of this potential annual adjustment for a few years, the production level of steelhead smolts supported by the two PUDs in the UCR basin will not increase during the duration of this Opinion. Reduction of production level could occur following survival studies and consensus of the HCP Coordinating Committee. The PUDs propose to potentially use some of the artificially propagated steelhead juveniles for dam passage survival studies pending recommendation and approval by the HCP Committees.

The PUDs propose to utilize agreements with other entities to implement hatchery obligations for the rearing, release, monitoring and evaluation, and research. The HCP Hatchery Committees must approve any proposed agreements or trades of production. However, it is the PUDs' responsibility to ensure that their obligations under Section 8 of the HCPs (Hatchery Compensation Plan) are satisfied.

The HCP Hatchery Committees will develop five-year monitoring and evaluation plans for the hatchery programs and update them every five years. The PUDs will fund the implementation of the monitoring and evaluation plans. The first monitoring and evaluation plan shall be developed by the HCP Hatchery Committees within one year of the issuance of the FERC order incorporating the HCPs into the PUDs' licenses. The monitoring plans will include data collection and analysis of all life stages of steelhead within the hatchery environment as well as data collection activities outside the hatchery facilities such as spawning ground surveys, juvenile fish traps, and adult traps and monitoring sites. Programs specific monitoring activities necessary to evaluate the programs will be determined by the HCP Hatchery Committees.

At this time, the ability to hold adult UCR steelhead in river water or water of appropriate temperature for maturation has been identified and the ability to rear juveniles on river water to produce the highest quality smolt has been identified as measures that the Chelan PUD need to address in the near term as program improvements in the two HCP agreements with Chelan PUD.

In the HCP agreements, the PUDs acknowledge that over the duration of the HCPs, new information and technologies that are developed will be considered and utilized in the monitoring and evaluation of the hatchery programs, where appropriate. The PUDs shall implement monitoring and evaluation of the hatchery programs consistent with the HCPs, the general objectives and guidelines listed for each Plan Species in the BAMP (1998), as determined by the HCP Hatchery Committees, and as analyzed in this Opinion. Monitoring and evaluation or research activities not considered here may require re-initiation of consultation depending on the potential effects of the activities.

2.2.3 Additional Terms and Conditions

The following additional terms and conditions will be incorporated into permit 1395 in order to minimize the potential adverse impacts associated with the proposed artificial propagation programs and are therefore part of the proposed action:

1. The Chelan PUD and Douglas PUD shall provide artificially propagated compensation of 400,000 and 349,000 yearling UCR steelhead smolts, respectively, as described in the three HCP agreements (CPUD 2002a; 2002b; DPUD 2002).

2. The Chelan PUD and Douglas PUD shall fund the specific elements of the artificial propagation programs objectives developed by the HCP Hatchery Committee, which may include contributing to the rebuilding and recovery of naturally reproducing populations in their native habitats, while maintaining genetic and ecologic integrity, and supporting harvest.

3. The Chelan PUD and Douglas PUD, in coordination with the HCP Hatchery Committees, shall develop five-year monitoring and evaluation plans for the hatchery programs that are updated every five years. The first monitoring and evaluation plans shall be completed within one year of the issuance of the FERC order incorporating the HCPs into the hydroproject operation licenses. Existing monitoring and evaluation programs shall continue until replaced by the HCP Hatchery Committees.

4. The Chelan PUD and Douglas PUD shall be responsive to new information and technologies that are developed, and approved by the HCP Hatchery Committees, which may be considered and utilized in the monitoring and evaluation of the artificial propagation programs, where appropriate.

5. The Chelan PUD and Douglas PUD shall fund artificial propagation program monitoring and evaluation consistent with the HCPs, the general objectives and guidelines listed for each Plan Species in the BAMP, this Opinion, and as determined by the HCP Hatchery Committees.

6. The Chelan PUD and Douglas PUD shall assume the lead, and work in coordination with the HCP Hatchery Committees, in developing the ten-year hatchery program reviews and directing the development of annual summary reports. The program reviews will determine if egg-to-fry, adult-to-smolt and smolt-to adult survival rates, and other appropriate hatchery program goals and objectives of the HCPs and the ESA section 10 permits have been met or sufficient progress is being made towards their achievement. This review shall include a determination of whether artificially propagated production objectives are being achieved.

7. The WDFW shall limit annual production of Wenatchee summer steelhead for release into the Wenatchee River to not exceed 400,000 juveniles at approximately 6 fish per pound released in April or May.

8. The WDFW shall limit annual production of steelhead for release into the Methow or Okanogan Rivers to not exceed 349,000 juvenile at approximately 6 fish per pound released in April or May.

9. The WDFW shall limit annual production of steelhead for release into the Columbia River from Ringold Springs Rearing Facility to 180,000 juveniles at approximately 6 fish per pound.

10. The WDFW may collect and retain 125,000 eggs for transfer to the U.S. Fish and Wildlife Service for eventual release into the Methow River as authorized in permit 1396.

11. The WDFW may retain eggs to meet a 150,000 steelhead juvenile production level in addition to the production levels identified above, following approval and recommendation of the production for use as dam passage survival study fish by the HCP Hatchery Committees.

12. The WDFW shall operate and manage the UCR steelhead artificial propagation programs including following impact minimization measures as proposed in section 2.1 of this Opinion.

13. To the extent possible without imposing increased risk to listed species, Chelan PUD, Douglas PUD, and WDFW shall enumerate and identify marks and tags on all anadromous species encountered at adult and juvenile trapping sites. This information should be included in either an annual brood program report or a monitoring and evaluation report submitted to NMFS.

14. In trapping operations directed at the collection of broodstock, the Permit Holders shall apply measures that minimize the risk of harm to listed salmon and steelhead. These measures include, but are not limited to: limitations on the duration (hourly, daily, weekly) of trapping in mainstem river areas to minimize capture and handling effects on listed fish; limits on trap holding duration of listed fish prior to release; application of procedures to allow safe holding, and careful handling and release of listed fish; and allowance for free passage of migrating listed fish through trapping sites in mainstem and tributary river locations when those sites are not being actively operated.

15. All artificially propagated UCR steelhead smolts shall be externally marked (i.e., visual implant elastomer tag or adipose fin clipped) prior to release.

16. At least a representative portion of the artificially propagated UCR steelhead smolts shall be internally tagged (e.g., CWT, PIT tag) prior to release to allow monitoring and evaluation of fish performance and contribution rates, including straying levels to natural spawning areas and to other hatcheries. The appropriate level of tagging shall be based in the investigational or management objectives and shall be reviewed by a trained statistician or biometrician.

17. ESA-listed juvenile fish must not be handled if the water temperature exceeds 21°C (69.8°F) at the capture site. Under these conditions, ESA-listed fish may only be identified and counted.

18. If water temperature at adult trapping sites exceeds 21°C (69.8°F), the trap the trap operation shall cease pending further consultation with NMFS to determine if continued trap operation poses substantial risk to ESA-listed species.

19. When radio or active tags or Petersen disk tags are applied, recreational harvest regulations will clearly and specifically identify these fish as not available for retention. Information concerning the application, tracking, and final disposition of fish with these tags shall be included in annual reports.

20. In years when harvest activities are implemented, the WDFW shall conduct regular enforcement patrols and include a summary of enforcement actions, including regulation compliance statistics, in the annual report described below.

21. The Permit Holders may conduct spawning ground and carcass surveys to assess the distribution and impact of artificially propagated UCR steelhead on the natural-origin steelhead populations.

22. The Permit Holders may capture, handle, and release up to 20 percent of the natural-origin steelhead juveniles in a tributary basin using standard juvenile fish trapping techniques such as rotary screw traps. Lethal take may not exceed two percent of the fish captured.

23. The WDFW shall develop annual broodstock collection and spawning protocols for the UCR Region ESA-listed steelhead artificial propagation programs. Protocols should be coordinated with the co-managers and HCP Hatchery Committee which must be submitted to NMFS Salmon Recovery Division by June 15th of the collection year.

24. The WDFW shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during trapping. The WDFW shall carefully handle and immediately release upstream incidentally captured listed UCR spring chinook salmon adults that are not intended for use as broodstock in concurrently operated and previously authorized listed stock recovery programs.

25. If enabled by identification of artificially propagated fish through external marking, measures should be applied to cull surplus hatchery-origin fish returning to a watershed in excess of program objectives.

26. The WDFW shall limit operation of Wells Dam east and west ladder traps to no more than three days per week from July through November. If both traps are operated, they shall be operated concurrently, operating on the same three days each week. When operating, active trapping may occur up to 16 hours per day. The ladder shall be open to passage at night to allow passage to listed steelhead.

27. Prior to opening any fishery targeting surplus artificially propagated UCR steelhead, the WDFW shall provide the proposed regulations to NMFS. The proposed regulations should include definition of the fishing areas, steelhead retention limits, anticipated encounter rate of natural-origin steelhead, estimated mortality impacts on natural-origin steelhead, monitoring plan, enforcement plans, and potential fisheries adjustments that would be made if impacts exceed authorized levels.

28. In years when harvest activities are implemented, the WDFW shall provide monthly reports by the 10th working day of the following month to NMFS. The report shall summarize the fishery activities, including angler effort, number of steelhead harvested, number of encounters with natural-origin UCR steelhead by tributary fishery area, and estimated UCR steelhead mortality impact; these reports shall include low enforcement information, particularly an estimate of illegal harvest and degree of regulation compliance. A final report detailing the fishery impacts by month and fishery area as described above shall be submitted to NMFS by August 31st of the year the fishery was concluded.

29. The WDFW shall manage artificially propagated steelhead returning to the Wenatchee River, Methow River, and Okanogan River basin tributary spawning areas in a manner consistent with recovery goals to enhance natural-origin populations. To reduce the number of artificially propagated UCR steelhead in the spawning areas in excess of full habitat seeding levels and to increase the proportion of the natural-origin steelhead in the tributary spawning populations, the WDFW may employ two methods. They may remove artificially propagated steelhead at dams or other trapping sites and they may use recreational fisheries to reduce the number of adipose fin-clipped hatchery-reared steelhead that may spawn naturally if the conditions described below are met:

i. Tier 1: When the natural origin UCR steelhead run is predicted to exceed 1,300 fish at Priest Rapids Dam and the total UCR steelhead run is predicted to exceed 9,550 steelhead, then a harvest fishery may be considered as an option to remove excess adipose fin clipped hatchery reared steelhead. For a fishery to be authorized in the tributary areas, the tributary escapements must be predicted to meet the minimum targets listed in Table 2, Tier 1. The mortality impact on natural origin UCR steelhead must not exceed the limits specified for Tier 1 in each tributary area.

ii. Tier 2: When the natural origin UCR steelhead run is predicted to exceed 2,500 fish at Priest Rapids Dam, the total UCR steelhead run is predicted to exceed 10,035 steelhead, and the tributary escapements meet the minimum targets listed in Table 2, Tier 2, then the natural origin UCR steelhead mortality impacts must not exceed the limits specified for Tier 2 for each tributary area.

iii. Tier 3: When the natural origin UCR steelhead run is predicted to exceed 3,500 fish at Priest Rapids Dam, and the total UCR steelhead run is predicted to exceed 20,000 steelhead, and the tributary escapements meet the minimum targets listed in Table 2, Tier 3, then the natural origin UCR steelhead mortality impacts must not exceed the limits specified for Tier 3 in each tributary area.

iv. The WDFW may remove artificially propagated steelhead at dams or other trapping sites to reduce the number of artificially propagated UCR steelhead in the spawning areas in excess of full habitat seeding levels to increase the proportion of the natural origin steelhead in the spawning population.

Table 2. Natural origin UCR steelhead run size criteria for recreational harvest fisheries in the Wenatchee River, Methow River, and Okanogan basin tributary spawning areas and mortality take limit of natural origin UCR steelhead. Catch and release mortality is estimated at 5 percent.

Tributary Area	Priest Rapids Dam Count	**Estimated Escapement to Tributary Area**	Mortality Impact
Wenatchee River and Columbia River above Rock Island Dam to below Rocky Reach Dam			
	<837	<599	0%
Tier 1	838	600	2%
Tier 2	2,146	1,700	4%
Tier 3	3,098	2,500	6%
Methow River and Columbia River above Wells Dam			
	<908	<499	0%
Tier 1	804	500	2%
Tier 2	2,224	1,600	4%
Tier 3	3,386	2,500	6%
Okanogan basin upstream of the Highway 97 Bridge			
	<175	<119	0%
Tier 1	176	120	5%
Tier 2	180	120	7%
Tier 3	795	600	10%

30. Adult return information shall include the most recent annual estimates of the number and proportion of artificially propagated fish on the spawning grounds, and the number and location of artificially propagated adults that were recovered outside the release areas. Adult return information and results from monitoring and evaluation activities outside the hatchery environment should be included in the annual report or a separate report. If a separate report on monitoring and evaluation activities conducted outside the hatchery environment is prepared, it shall be submitted by August 31st, of the year following the monitoring and evaluation activities (i.e., surveys conducted in 2003, report due August 2004) to NMFS Salmon Recovery Division, Portland, Oregon.

31. In years when harvest fisheries are implemented, the WDFW shall provide monthly reports by the 10th working day of the following month to NMFS Salmon Recovery Division in Portland, Oregon. The report shall summarize the fishery activities including angler effort, harvest, encounters with natural origin UCR steelhead by tributary fishery area, and estimated UCR steelhead mortality impact. A final report detailing the fishery

impacts by month and fishery area shall be submitted to NMFS Salmon Recovery Division in Portland Oregon by August 31st of the year the fishery was concluded.

32. In years when harvest fisheries are implemented, the WDFW shall conduct regular enforcement patrols and include a summary of enforcement actions, including regulation compliance statistics in the annual report described above.

2.3 Permit 1396 - U.S. Fish and Wildlife Service

NMFS proposes to issue permit 1396 to the USFWS to carry out a program artificially propagating endangered UCR steelhead in the Methow River. Program details were provided in a permit application (USFWS 2002) and are summarized below, followed by additional terms and conditions to be included in permit 1396.

2.3.1 Proposed Activities

The USFWS at Winthrop NFH proposes to obtain 125,000 eyed-eggs or fry from the WDFW Wells Hatchery for rearing and release into the Methow River annually. Two transfer options are proposed: (1) Eyed eggs taken from throughout the run would be transferred to Winthrop NFH in egg transport containers loaded in a covered truck in March, or (2) fry from eggs taken from throughout the run would be transported to Winthrop NFH in July at a size of 180 to 300 fish per pound. Fish would be transported from Wells Hatchery using fish transportation trucks equipped with aeration devices, oxygen tanks, air stones, and recirculating pumps.

At the beginning of September of each year, under both of the above scenarios, the fish will be reared to maintain a density index at or below established criteria. Water source is screened Methow River water, pumped ground water, or a combination of both. The fish remain in the six ponds until their April release into the Methow River when they average 5 to 8 fish per pound. The USFWS proposes to externally mark all smolts with an adipose fin-clipped to identify them as hatchery origin. The proposed release of 100,000 smolts would occur as a volitional release from the raceways, from which smolts would migrate into a channel fed by a spring and overflow hatchery water and enter the Methow River about 1/4 mile downstream from the hatchery facility.

2.3.2 Additional Terms and Conditions

The following additional terms and conditions will be incorporated into permit 1396 in order to minimize the potential adverse impacts associated with the proposed artificial propagation program:

1. The USFWS may receive up to 125,000 eggs from the WDFW as authorized in permit 1395

2. The USFWS shall limit annual production of steelhead for release into the Methow River to not exceed a total of 100,000 juveniles at approximately 6 fish per pound release in April or May.

3. The USFWS shall externally mark artificially propagated steelhead groups released into the Methow River with an adipose fin clip. All marking programs shall be coordinated with other fish production agencies within the Columbia River Region.

4. The USFWS shall internally tag (e.g., CWT, PIT tag) at least a representative sample of artificially propagated steelhead groups released into the Methow River to allow monitoring and evaluation of fish performance and contribution rates, including straying levels to natural spawning areas and to other hatcheries. All tagging programs shall be coordinated with other fish production agencies within the Columbia River Region.

2.4 Permit 1412 - Confederated Tribes of the Colville Reservation

NMFS proposes to issue permit 1412 to the Colville Tribes to carry out an artificial propagation research and enhancement program to enhance the natural origin UCR steelhead in the Okanogan River basin. Program details were provided in the permit application (CCT 2002) and are summarized below, followed by additional conditions that will be included in the permit.

2.4.1 Proposed Activities

The Colville Tribes propose to install a temporary picket weir in Omak Creek in mid-March through April 30th annually at approximately rm 0.5 to collect about 16 adult steelhead for broodstock. The Colville Tribes further proposed to install a permanent trap in Omak Creek in the future pending additional funding and submittal of a Biological Assessment. The permanent trap will not be analyzed at this time. If the picket weir is not successful, then trap nets or angling would be used to collect broodstock. The broodstock would be transported approximately 35 miles in a tank truck to the Colville Tribal Trout Hatchery, near Bridgeport, Washington.

Adult steelhead would be spawned and biologically sampled according to standardized fish health practices following fish disease control guidelines developed by IHOT (1995) and the PNFHPC (1989). Fin tissue and other biological data would be collected from the broodstock to monitor the program impacts.

Eggs would be incubated and juvenile fish reared at the tribal facility until the yearling smolt stage. Fish health would be monitored routinely, generally on a monthly schedule, and the rearing facility would be operated to be in compliance with "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" standards (NWIFC and WDFW 1998).

Juvenile fish would be biologically sampled in the hatchery facility including collection of fin tissue for genetic monitoring, and growth monitoring.

Juvenile steelhead would be externally marked with visual implant elastomer tags for identification purposed but not adipose fin-clipped. Juveniles may also be PIT tagged for identification purposes. Steelhead smolts with a demonstrated preparedness for downstream migration would be released into Omak Creek from a Natural Rearing Enhancement System (NATURES)-type acclimation pond, which is in development with a completion target date of spring 2004, or scatter-planted from a tank truck in April or May.

2.4.2 Additional Terms and Conditions

The following additional terms and conditions will be incorporated into permit 1412 in order to minimize the potential adverse impacts of the proposed artificial propagation programs:

1. The Colville Tribes shall limit annual production of steelhead for release into the Okanogan River basin to not exceed 40,000 yearlings to be released in April or May.

2. In the event that circumstances, such as unanticipated, higher-than-expected fecundity, and high egg to fry survival rates, lead to the inadvertent possession of steelhead substantially in excess (>110 %) of program goal levels, surplus eggs or fish shall be culled from the population in a random manner.

3. To the extent possible without imposing increased risk to listed species, the Colville Tribes shall enumerate, and identify marks and tags on, all anadromous species encountered at adult trapping sites. This information should be included in the either an annual brood program report or a monitoring and evaluation report submitted to NMFS, Salmon Recovery Division, Portland, Oregon.

4. The Colville Tribes shall apply measures in trapping operations directed at the collection of broodstock that minimize the risk of harm to listed salmon and steelhead. These measures include, but are not limited to: limitations on the duration (hourly, daily, weekly) of trapping in mainstem river areas to minimize capture and handling effects on listed fish; limits on trap holding duration of listed fish prior to release; application of procedures to allow safe holding and careful handling and release of listed fish; and allowance for free passage of migrating listed fish through trapping sites in mainstem and tributary river locations when those sites are not being actively operated.

5. Traps to collect or monitor UCR steelhead must be checked, and all fish removed at least daily.

6. The Colville Tribes shall externally mark artificially propagated steelhead groups released into Omak Creek. All marking programs shall be coordinated with other fish production agencies within the Columbia River Region.

7. The Colville Tribes shall, if funding can be secured, periodically internally tag (e.g., CWT, PIT tag) at least a representative sample of artificially propagated steelhead groups released into the UCR basin to allow monitoring and evaluation of fish performance and contribution rates, including straying levels to natural spawning areas and to other hatcheries. All tagging programs shall be coordinated with other fish production agencies within the Columbia River Region.

8. If water temperature at adult trapping sites exceeds 21°C (69.8°F), the trap operating entity shall notify NMFS to determine if continued trap operation poses substantial risk to ESA-listed species.

9. The Colville Tribes shall provide an annual report that summarizes numbers, pounds, dates, tag/mark information, locations of artificially propagated fish releases, monitoring and evaluation activities that occur within the hatchery environment, and adult return to the UCR basin for each program. The Colville Tribes shall collect and report the coefficient of variation around the average (target) steelhead release size immediately prior to their liberation from the acclimation sites as an indicator of population size uniformity and smoltification status. Unless otherwise noted in the specific terms and conditions, the reports shall be submitted by January 31st of the year following release (i.e., brood year 2001, release year 2002, report due January 2003) to NMFS Salmon Recovery Division, Portland, Oregon.

10. Adult return information should include the most recent annual estimates of the number and proportion of artificially propagated fish on the spawning grounds, and the number and location of artificially propagated adults that were recovered outside the release areas. Adult return information and results from monitoring and evaluation activities outside the hatchery environment should be included in the annual report or a separate report. Unless otherwise noted in the specific terms and conditions, if a separate report on monitoring and evaluation activities conducted outside the hatchery environment is prepared, it shall be submitted by August 31st, of the year following the monitoring and evaluation activities (i.e., surveys conducted in 2003, report due August 2004) to NMFS.

2.5 Action Area

The action area is defined as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR §402.02).

Direct effects of the proposed action of the issuance of all three permits would occur within the UCR basin and includes areas primarily in Chelan, Douglas, and, Okanogan counties; more specifically, the Columbia River at and above Priest Rapids Dam, the Wenatchee River, Methow River, and Okanogan River basins and artificial propagation facilities along the mainstem Columbia River (Figure 1).

The effected area in the Wenatchee River basin includes the Chiwawa River, Nason Creek, Dryden and Tumwater Dams, and all tributaries accessible to anadromous steelhead. The effected area in the Methow River basin includes the Methow River, Twisp River, Chewuch River, the Methow Hatchery, the Winthrop NFH, and various smaller tributaries that are accessible to steelhead. The effected area in the Okanogan River basin includes the Okanogan River, Similkameen River, Omak Creek, and Salmon Creek, and other small tributaries that are accessible to steelhead. The effected area in the Columbia River basin includes the Wells, Ringold, Eastbank and Chelan hatcheries and the ladder traps at Wells and Priest Rapids dams.

Critical habitat was designated for UCR steelhead in 2000 when NMFS published a final rule in the Federal Register (65 FR 7764). However, the critical habitat designation for UCR steelhead was vacated and remanded to NMFS for new rulemaking pursuant to a court order in April 2002. The designation of critical habitat for the UCR steelhead ESU will trigger a reinitiation of ESA consultation.

3. STATUS OF SPECIES UNDER THE ENVIRONMENTAL BASELINE

In order to describe a species' status, it is first necessary to define precisely what "species" means in this context. Traditionally, one thinks of the ESA listing process as pertaining to entire taxonomic species of animals or plants. While this is generally true, the ESA also recognizes that there are times when the listing unit must necessarily be a subset of the species as a whole. In these instances, the ESA allows a "distinct population segment" (DPS) of a species to be listed as threatened or endangered. UCR steelhead and spring chinook salmon are just such DPSs and, as such, are for all intents and purposes considered "species" under the ESA.

NMFS developed the approach for defining salmonid DPSs in 1991 (Waples 1991). It states that a population or group of populations is considered distinct if they are "substantially reproductively isolated from conspecific populations," and if they are considered "an important component of the evolutionary legacy of the species." A distinct population or group populations is referred to as an evolutionarily significant unit (ESU) of the species. Hence, UCR steelhead constitute an ESU of the species *O. mykiss,* and UCR spring chinook salmon are an ESU of *O. tshawytscha*.

On March 24, 1999, NMFS listed UCR spring chinook salmon as an endangered species under the ESA (64 FR 14308). In its final listing determination, NMFS concluded that the UCR spring chinook salmon ESU is in danger of extinction throughout all or a significant portion of its range. NMFS also determined that six hatchery stocks in the UCR Basin (Chiwawa, Methow, Twisp, Chewuch, and White Rivers and Nason Creek) should be considered part of the ESU because they are currently essential for the recovery of the ESU. The WDFW operates most of the artificial propagation programs for listed UCR spring chinook salmon.

On August 18, 1997, NMFS listed UCR steelhead as an endangered species under the ESA (62 FR 43937). NMFS concluded that the UCR steelhead ESU is in danger of extinction throughout all or a significant portion of its range. NMFS also determined that one hatchery stock in the UCR basin, the Wells Hatchery stock, should be considered part of the ESU because it is currently essential for the recovery of the ESU. All artificial propagation programs rearing steelhead in the UCR were derived from the Wells Hatchery stock and natural origin UCR steelhead and are considered part of the ESU.

The UCR spring chinook salmon and steelhead were listed because NMFS determined that a number of factors—both environmental and demographic—had caused them to decline to the point where they were likely to become extinct within the foreseeable future. These factors for decline affect UCR chinook salmon and steelhead biological requirements at every life stage and they arise from a number of different sources. This section of the Opinion explores those effects and defines the context within which they take place.

To determine a species' status under extant conditions (usually termed "the environmental baseline"), it is necessary to ascertain the degree to which the species' biological requirements are being met at that time and in that action area. For the purposes of this consultation, UCR spring chinook salmon and steelhead biological requirements are expressed in two ways: Population parameters such as fish numbers, distribution, and trends throughout the action area; and the condition of various essential habitat features such as water quality, stream substrates, and food availability. Clearly, these two types of information are interrelated. That is, the condition of a given habitat has a large impact on the number of fish it can support. Nonetheless, it is useful to separate the species' biological requirements into these parameters because doing so provides a more complete picture of all the factors affecting UCR spring chinook salmon and UCR steelhead survival. Therefore, the discussion to follow will be divided into two parts: Species Distribution and Trends; and Factors Affecting the Environmental Baseline.

3.1 Species Distribution and Trends

3.1.1 Chinook Salmon

Chinook salmon are the largest of the Pacific salmon. The species' North American distribution historically ranged from the Ventura River in California to Point Hope, Alaska. In northeastern Asia, the species range from Hokkaido, Japan, to the Anadyr River in Russia (Healey 1991).

Additionally, chinook salmon have been reported in the Mackenzie River area of northern Canada (McPhail and Lindsey 1970). Of the Pacific salmon, chinook salmon exhibit the most diverse and complex life-history strategies. Healey (1986) described 16 age categories for chinook salmon, seven total ages at maturity with three possible freshwater ages. Gilbert (1912) initially described two general freshwater life-history types: "stream-type" chinook salmon reside in fresh water for a year or more following emergence; "ocean-type" chinook salmon migrate to the ocean within their first year. Healey (1983, 1991) has promoted the use of broader definitions for "ocean-type" and "stream-type" to describe two distinct races of chinook salmon. This racial approach incorporates life history traits, geographic distribution, and genetic differentiation and provides a valuable frame of reference for comparisons of chinook salmon populations. The generalized life history of Pacific salmon includes freshwater phases of incubation, hatching, emergence, migration to the ocean, rearing in marine waters, and subsequent initiation of maturation and return to fresh water for completion of maturation and spawning. Juvenile rearing in fresh water can be minimal or extended. Additionally, some male chinook salmon mature in fresh water, thereby foregoing emigration to the ocean. The timing and duration of each of these stages is related to varying degrees of genetic and environmental determinants and interactions thereof. Chinook salmon may spend one to six years in the ocean before returning to their natal streams to spawn.

Ocean distribution differs between ocean- and stream-type chinook salmon (Healey 1983, 1991). Ocean-type chinook salmon tend to migrate along the coast, and stream-type chinook salmon migrate far from the coast in the central North Pacific. Chinook salmon populations can be characterized by their time of freshwater entry as spring, summer, or fall runs. Spring chinook salmon tend to enter freshwater and migrate far upriver, where they hold and become sexually mature before spawning in the late summer and early autumn. Fall chinook salmon enter freshwater in a more advanced stage of sexual maturity, move rapidly to their spawning areas on the mainstem or lower tributaries of their natal rivers and spawn within a few days or weeks of freshwater entry (Fulton 1968, Healey 1991). Summer chinook salmon are intermediate between spring and fall runs, spawning in large and medium-sized tributaries, and not showing the extensive delay in maturation exhibited by spring chinook salmon (Fulton 1968).

3.1.1.1 UCR Spring Chinook Salmon

The UCR spring chinook salmon ESU, listed as endangered on March 24, 1999 (64 FR 14308), includes all natural-origin stream-type chinook salmon from river reaches above Rock Island Dam and downstream of Chief Joseph Dam, including the Wenatchee, Entiat, and Methow River basins (Myers *et al.* 1998). All chinook salmon in the Okanogan River are apparently ocean-type and are considered part of the UCR summer/fall run ESU. Nine stocks have been identified within the UCR spring chinook salmon ESU (WDF *et al.* 1993). All stocks, with the exception of the Methow stock, were considered by WDF *et al.* (1993) to be of native origin, of natural production type, and as depressed in status. The WDFW considers the Methow spring chinook salmon stock to be a composite in production type, but of native origin, and depressed in status.

When listing the UCR spring chinook salmon as endangered NMFS included six hatchery populations as part of the ESU: Chewuch River, Methow River, Twisp River, Chiwawa River, White River and Nason Creek. These six hatchery populations were considered to be essential for recovery and were therefore listed as part of the ESU. Hatchery populations at Winthrop NFH, Entiat NFH, and Leavenworth NFH were not included as part of the ESU because they were derived from Carson NFH spring chinook salmon.

The UCR spring chinook salmon have a stream-type life history. Adults return to the Wenatchee River during late March through early May, and to the Entiat and Methow Rivers during late March through June. Most adults return after spending 2 years in the ocean, although 20 to 40 percent return after three years at sea. The UCR spring chinook salmon experience very little ocean harvest. Peak spawning for all three populations occurs from August to September. Smolts typically spend one year in freshwater before migrating downstream. There are slight genetic differences between this ESU and others containing stream-type fish, but more importantly, the ESU boundary was defined using ecological differences in spawning and rearing habitat (Myers *et al.* 1998). The Grand Coulee Fish Maintenance Project (1939 through 1943) may have had a major influence on this ESU because fish from multiple populations were mixed into one relatively homogenous group and redistributed into streams throughout the UCR region. A more detailed discussion of UCR spring chinook salmon is provided in the Biological Opinion concerning spring chinook salmon artificial propagation programs (NMFS 2000a).

NMFS recently proposed Interim Recovery Abundance Levels and Cautionary Levels (Ford *et al*. 2001). *Cautionary Levels* were characterized as abundance levels that the population fell below only about 10 percent of the time during a historical period when it was considered to be relatively healthy. The three independent populations of spring chinook salmon identified for the ESU include those that spawn in the Wenatchee, Entiat, and Methow basins (Ford *et al.* 2001).

All three of the existing UCR spring chinook salmon populations have exhibited similar trends and patterns in abundance over the past 40 years. The 1998 status review (Myers et al. 1998) reported that long-term trends in abundance were generally negative, ranging from -5 to +1 percent. Analyses of the data series, updated to include 1996-2001 returns, indicate that those trends have continued. Based on redd count data series, spawning escapements for the Wenatchee, Entiat, and Methow rivers have declined an average of 5.6, 4.8, and 6.3 percent per year, respectively, since 1958. In the most recent five year geometric mean (1997-2001), spawning escapements were 273 for the Wenatchee population, 65 for the Entiat population, and 282 for the Methow population, only 8 to 15 percent of the interim abundance recovery targets, although escapement increased substantially in 2000 and 2001 in all three river systems. Based on 1980-2000 returns, the average annual growth rate for this ESU is estimated as 0.85. Assuming that population growth rates were to continue at 1980-2000 levels, UCR spring chinook salmon populations are projected to have very high probabilities of 90 percent decline within 50 years (87 to 100 percent).

Summary

While some improvement can be seen in recent years, the ESU is still at critically low levels compared to both historic production and the desired escapement levels—particularly for natural fish. Therefore, while there is some cause for very guarded optimism, NMFS finds that there has been no genuine change in the species' status since they were listed as endangered, and the biological requirements are not being met with respect to abundance, distribution, or overall trend.

3.1.2 Steelhead

Steelhead can be divided into two basic run types based on their level of sexual maturity at the time they enter fresh water and the duration of the spawning migration (Burgner *et al*. 1992). The stream-maturing type, or summer steelhead, enters fresh water in a sexually immature condition and requires several months in fresh water to mature and spawn. The ocean-maturing type, or winter steelhead, enters fresh water with well-developed gonads and spawns relatively shortly after river entry (Barnhart 1986). Variations in migration timing exist between populations. Some river basins have both summer and winter steelhead, others only have one run type. Unlike Pacific salmon, steelhead are iteroparous, or capable of spawning more than once before death. However, it is rare for steelhead to spawn more than twice before dying, and most that do so are females (Nickelson *et al.* 1992). Iteroparity is more common among southern steelhead populations than northern populations (Busby *et al.* 1996). Multiple spawnings for steelhead range from three percent to 20 percent of runs in Oregon coastal streams. Steelhead spawn in cool, clear streams with suitable gravel size, depth, and current velocity. Intermittent streams may also be used for spawning (Barnhart 1986, Everest 1973).

Based on catch data, juvenile steelhead tend to migrate directly offshore during their first summer, rather than migrating nearer to the coast as do salmon. During fall and winter, juveniles move southward and eastward (Hartt and Dell 1986). Available fin-mark and coded-wire tag data suggests that winter steelhead tend to migrate farther offshore but not as far north into the Gulf of Alaska as summer steelhead (Burgner *et al.* 1992). Maturing Columbia River steelhead are found off the coast of Northern British Columbia and west into the North Pacific Ocean (Busby *et al.* 1996). At the time adults are entering freshwater, tagging data indicate that immature Columbia River steelhead are out in the mid-North Pacific Ocean.

3.1.2.1 UCR Steelhead

The UCR steelhead ESU, listed as endangered on August 18, 1997 (62 FR 43937), includes all natural-origin populations of steelhead in the Columbia River basin upstream from the Yakima River, Washington, to the U.S./Canada border. The Wells Hatchery steelhead stock is considered essential for recovery, and is included in the listing.

The Wells hatchery stock is considered part of the UCR ESU because it was founded from a mixture of native populations and retains genetic resources of steelhead populations above Grand

Coulee Dam that are now extinct. Since 1997, the WDFW has been developing a Wenatchee River stock for the juvenile released into the Wenatchee basin. Currently, there is probably a close resemblance between the natural and hatchery populations in this ESU because of the incorporation of naturally-spawning adults into the hatchery program and the large number of hatchery fish that have been spawning in the natural environment (65-80 percent of the spawning population in the Methow basin; Busby *et al.* 1996). Since natural replacement rates of UCR steelhead are low (0.3:1), the hatchery supplementation programs were determined to be essential for recovery and included in the endangered listing under the ESA. These hatchery fish could be used to reduce the short-term risk of extinction and aid in the recovery of the UCR steelhead ESU.

Although the life history of this ESU is similar to that of other inland steelhead, smolt ages are some of the oldest on the west coast (up to 7 years old), probably due to the ubiquitous cold water temperatures (Mullan *et al.* 1992). Adult steelhead from this ESU enter the lower Columbia between May and September with fish arriving at Wells Pool in early July. Fish enter the Wenatchee and Methow Rivers in mid-July and peak between mid-September and October. During winter, adult steelhead generally return to the warmer Columbia River and re-enter the Methow to begin spawning in mid-March after the ice has thawed. Spawning continues through May and many fish seek out higher reaches in the tributaries. Fry emergence occurs that summer and juveniles rear for two to four years prior to spring downstream migration.

On April 4, 2002, NOAA Fisheries defined interim abundance recovery targets for each spawning population in this ESU (Lohn 2002). These targets are intended to represent the number and productivity of naturally produced spawners that may be needed for recovery, in the context of whatever take or mortality is occurring. They should not be considered in isolation, as they represent the numbers that, taken together, may be needed for the population to be self-sustaining in its natural ecosystem. For UCR steelhead, the interim recovery levels are 2,500 spawners in the Wenatchee River, 500 spawners in the Entiat River, and 2,500 spawners in the Methow River (Lohn 2002).

Returns of both hatchery and naturally produced steelhead to the UCR basin have increased in recent years. The average 1997-2001 return counted through the Priest Rapids Dam fish ladder was approximately 12,900 fish. The average for the previous five years (1992-1996) was 7,800 fish. Abundance estimates of returning naturally produced UCR steelhead have been based on extrapolations from mainstem dam counts and associated sampling information (e.g., hatchery/natural fraction, age composition). The natural component of the annual steelhead run over Priest Rapids Dam increased from an average of 1,040 (1992-1996), representing about 15 percent of the total adult count, to 2,200 (1997-2001), representing about 17 percent of the adult count during this period of time (BRT 2003).

In terms of natural production, recent population abundances for both the Wenatchee/Entiat river aggregate population and the Methow population remain well below the interim recovery levels developed for these populations (BRT 2003). A 5-year geometric mean (1997-2001) of

approximately 900 naturally produced steelhead returned to the Wenatchee and Entiat rivers (combined) compared to a combined abundance target of 3,000 fish. Although this is well below the interim recovery target, it represents an improvement over the past (an increasing trend of 3.4 percent per year). However, the average percentage of natural fish for the recent 5-year period dropped from 35 to 29 percent, compared to the previous status review. For the Methow population, the 5-year geometric mean of natural returns over Wells Dam was 358. Although this is well below the interim recovery target, it represents an improvement over the past (an increasing trend of 5.9 percent per year). In addition, the estimated 2001 return (1,380 naturally produced spawners) was the highest single annual return in the 25-year data series. However, the average percentage of natural origin spawners dropped from 19 percent for the period prior to the 1998 status review to 9 percent for the 1997 to 2001 returns.

Naturally produced steelhead made up an average of 17.8 percent of the steelhead run at Priest Rapids Dam during the 18-year period from 1986 to 2001 (Table 3). These natural origin steelhead are not equally distributed among the UCR tributary basins. Mullen *et al*. (1994) reported annual escapement to the Methow basin at only 10 percent natural origin steelhead; however, in recent years the WDFW (2002) report natural origin steelhead composition of 5 to 11 percent in 1998 through 2000 at Wells Dam (Table 4). The escapement to the Wenatchee basin from 1998 to 2000 averages 430 natural origin steelhead.

Table 3. Upper Columbia River steelhead run at Priest Rapids Dam from 1986 to 2002.

	Artificially Propagated		Naturally Produced		
Year	Total	Percent	Number	Percent	Total Run
1986	20,022	90%	2,342	10%	22,364
1987	9,955	71%	4,058	29%	14,013
1988	7,530	74%	2,670	26%	10,200
1989	8,033	75%	2,685	25%	10,718
1990	6,252	80%	1,585	20%	7,837
1991	11,169	80%	2,799	20%	13,968
1992	12,102	88%	1,618	12%	13,720
1993	4,538	84%	890	16%	5,428
1994	5,880	87%	855	13%	6,735
1995	3,377	77%	993	23%	4,370
1996	7,757	90%	843	10%	8,600
1997	8,157	91%	785	9%	8,942
1998	4,919	84%	928	16%	5,847
1999	6,903	83%	1,374	17%	8,277
2000	9,023	79%	2,341	21%	11,364
2001	24,174	81%	5,670	19%	29,844
Average	**9,362**	**82.2%**	**2,027**	**17.8%**	**11,389**

Table 4. Upper Columbia River steelhead run composition at Wells Dam (Methow and Okanogan basins) (Letter from Kirk Truscott, WDFW, July 9, 2003).

	Artificially Propagated		Naturally Produced		
Year	Number	Percent	Number	Percent	Total Run
1998	2,849	92%	234	8%	3,083
1999	3,511	89%	447	11%	3,958
2000	6,142	92%	541	8%	6,683
2001	18,034	95%	889	5%	18,923
2002	9,098	93%	706	7%	9,804

Artificially propagated steelhead have been released into tributary areas with good quality habitat to encourage their return and eventual spawning in the natural environment. In recent years artificial propagation has focused on incorporating natural origin fish into the broodstock populations.

Upper Columbia River steelhead migration and dam passage characteristics were evaluated using radio tags implanted at Priest Rapids Dam in 1999 and 2001 (English *et al*. 2001, 2003). Radio tagged fish were subsequently released 7.9 rm downstream of the dam. Of the steelhead tagged in 1999 and 2001, 75 and 81 percent were identified by marks and tags and originating from artificial propagation programs, respectively.

The distribution of radio tagged steelhead provides insight into the migration characteristics and spawning site selection. Based on marks and tags identified on and in steelhead at the time of tagging, 201 steelhead that were expected to return to the Methow or Okanogan basins remained in the system to spawn naturally. Of these, 72 percent actually went to the Methow or Okanogan, 5 percent strayed to rivers below Wells Dam, and 22 percent were last tracked in the Columbia River. A total of 32 radio-tagged steelhead were expected to return to the Wenatchee River basin, based on marks and tags. Of these, 66 percent (21 fish) went to the Wenatchee, 19 percent (6 fish) went to the Methow or Okanogan, and 16 percent (5 fish) were last tracked in the Columbia River (English *et al*. 2001, 2003).

The radio telemetry study also indicated that 56 to 73 percent of the steelhead that spawned attempted to return to the ocean in 2002 (tagged in 2001) as kelts. Of the 170 tributary spawners that were subsequently tracked as kelts, 18 percent (30 fish) were detected at or below Coyote Rapids in the Hanford Reach area below Priest Rapids Dam.

Radio tagged steelhead, both hatchery origin and natural origin, were tracked through the spawning season into the Wenatchee, Methow, Okanogan river basins as well as the Entiat,

Yakima, Snake river basins. In 2001-2002, a total of 77 and 61 percent of the hatchery and natural origin steelhead tagged were tracked through spawning, respectively. Both hatchery and natural origin steelhead were located in each of the major basins of the UCR. Distribution of hatchery and natural origin steelhead was similar. Natural origin fish returns were most frequently observed in the Wenatchee basin (37 percent) and Methow basin (35 percent).

Summary

While some improvement can be seen in recent years, the ESU is still at critically low levels compared to both historic production and the desired escapement levels of natural origin UCR steelhead. Therefore, while there is some cause for very guarded optimism, there has been no genuine change in the species' status since they were listed as endangered, and based on the best available science, NMFS finds that the biological requirements are not being met with respect to abundance, distribution, or overall trend.

3.2 Factors Affecting the Environmental Baseline in the Action Area

Environmental baselines for biological opinions are defined by regulation at 50 CFR §402.02, which states that an environmental baseline is the physical result of all past and present state, Federal, and private activities in the action area along with the anticipated impacts of all proposed Federal projects in the action area (that have already undergone formal or early section 7 consultation). The environmental baseline for this biological opinion is therefore the result of the impacts a great many activities (summarized below) have had on UCR steelhead and spring chinook salmon survival and recovery. Put another way, the baseline is the culmination of the effects that multiple activities have had on the species' biological requirements and, by examining those individual effects, it is possible to derive the species' status in the action area.

The best scientific information presently available demonstrates that a multitude of factors, past and present, have contributed to the decline of west coast salmonids by adversely affecting these essential habitat features. These factors are well known and documented in dozens—if not hundreds—of scientific papers, policy documents, news articles, books, and other media. It is therefore unnecessary to detail in this opinion the many ways in which human activities and natural factors have affected the UCR steelhead's and chinook salmon's habitat-related biological requirements; thus the following paragraphs constitute a brief summary of what the most recent accepted science has to say about how human action and natural processes have degraded essential steelhead habitat features in the UCR subbasin.

Some factors in the action area (e.g., hydropower and agricultural development—particularly irrigation diversions) have had adverse effects on the habitat-related biological requirements of UCR spring chinook salmon and UCR steelhead, while other factors have only affected some of those essential habitat features. For example, road building in the UCR subbasin has had a sizeable effect on stream substrates and water quality (through siltation), and road culverts have blocked fish passage, but such activities have not had much of an effect on water velocity. In another instance, timber harvest and grazing activities have affected—to greater or lesser

degrees—all the factors except space. And urban development has affected them all, but generally to a small degree in the largely rural UCR subbasin. In short, nearly every widespread human activity in the basin has adversely affected some or all of the habitat features. And by disrupting those habitat features, these activities—coupled with past hatchery and fishery effects and occasional natural disturbances such as drought and fire—have had detrimental impacts on UCR steelhead and spring chinook salmon health, physiology, numbers, and distribution in virtually every subpopulation and at every life stage. For detailed information on how various factors have degraded essential habitat features in the UCR subbasin, please see any of the following: NMFS (1991), NMFS (1997), NMFS (1998), NMFS (2000a), and, in particular, NMFS (2000b).

Summary

In conclusion, the picture of whether UCR steelhead and spring chinook salmon biological requirements are being met is more clear-cut for habitat-related parameters than it is for population factors: given all the factors for decline, it is clear that the UCR steelhead and spring chinook salmon biological requirements are currently not being met under the environmental baseline. Thus their status is such that a substantial improvement in the environmental conditions of their habitat is needed (over those currently available under the environmental baseline). Any further degradation of the environmental conditions could have a large impact because the species is already at risk of going extinct. In addition, there must be efforts to minimize impacts caused by dams, harvest, hatchery operations, habitat degradation, and unfavorable natural conditions.

4. ANALYSIS OF THE EFFECTS

NMFS analyzes the direct and indirect effects on an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action that will be added to the environmental baseline. Indirect effects are those that are caused by the proposed action and are later in time, but still are reasonably certain to occur. Interrelated action are those that are part of a larger action and depend on the larger action for the justification. Inter dependent actions are those that have no independent utility apart from the action under consideration (50 CFR §402.02).

The proposed actions can be divided into four categories, with specific activities in each category summarized in Table 5. Each of these activity categories has potential to effect ESA-listed UCR spring chinook salmon and UCR steelhead. The ESA section 10(a)(1)(A) process includes applicant proposed measures, and terms and conditions proposed by NMFS which function together to be protective of listed species. This section considers the potential effects of the proposed actions in the four activity categories above on the two ESA-listed ESUs that occur in the action area.

ble 5. Summary of activities that would be conducted if Permits 1395, 1396, and 1412 are issued.

e of Activity	Permit 1395	Permit 1396	Permit 1412	Potential Effects
lt Return nitoring	Intercept and collect biological data (length, scales, marks, tags, etc.) on 10 percent of run Externally tag sampled steelhead Summarize, assess, and report data collected	Not applicable	Not applicable	Mortality due to stress fro capture, handling, release Injury or mortality from tagging
lt Return agement	Ensure the run can fully seed the habitat in each basin Develop broodstock collection protocols Determine if excess hatchery steelhead should be removed from spawning populations in each basin	Not applicable	Not applicable	Swamping impacts on natural origin UCR steelhead Mortality from capture an release in fisheries
ficial pagation	Collect up to 373 broodstock fish at Wells Dam on the Columbia River for Methow and Okanogan basin releases Collect up to 208 broodstock fish at Dryden and Tumwater Dams for Wenatchee basin releases Collect up to 55 broodstock fish for PUD survival studies is some years Holding and artificial spawning of broodstock at Wells and Eastbank Hatcheries Transfer of 125,000 eyed-eggs or fry from W ells Hatchery to Winthrop National Fish Hatchery annually	Receive up to 125,000 eggs or fry from WDFW annually	Collect up to 16 adult steelhead for broodstock from Omak Creek or Okanogan River Holding and artificial spawning of broodstock at Colville Trout Hatchery	Numeric reduction of natural origin UCR steelhead spawners becau they are collected for broodstock

4.1 Effects of Proposed Action on UCR Spring Chinook Salmon

The potential effects in the form of incidental take of the proposed action on UCR spring chinook salmon is evaluated in this section. Organized by the four categories listed above. Where appropriate, the applicants propose minimization techniques to reduce incidental impacts on UCR spring chinook salmon.

4.1.1 Adult Return Monitoring

Monitoring of adult steelhead returns to the UCR basin at Priest Rapids Dam (rm 397), which is below the four steelhead production tributaries of the UCR basin will impact the target UCR steelhead, and potentially impact ESA-listed UCR spring chinook salmon. The migration timing of steelhead at Priest Rapids begins in late June and continues through November 15th when adult counting at the facility is terminated for the season (http://www.fpc.org/). Spring chinook salmon migration at Priest Rapids Dam occurs between about April 15th and June 15th. Adult steelhead return monitoring activities at Priest Rapids Dam generally begin the second week of July and ends about November 15th, which encompasses 95% of the run (Figure 2). The temporal separation between the two ESA-listed species run timing results in no anticipated effects on spring chinook salmon from steelhead adult monitoring at this location.

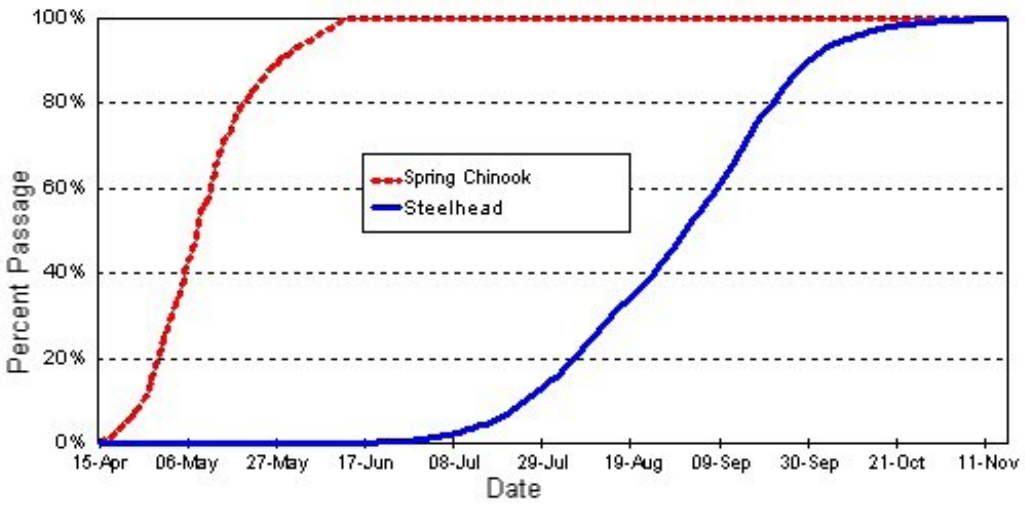

Figure 3. Ten year average cumulative passage of spring chinook salmon and steelhead at Priest Rapids Dam.

4.1.2 Adult Return Management

Management activities such as removal of excess artificially produced adult steelhead at trap sites or via recreational harvest fisheries could occur from October through March. Spring chinook salmon adults return to the UCR beginning in late March and complete spawning by the

end of September. The temporal separation in life history strategies result in no anticipated impacts of adult steelhead management or broodstock collection activities. Additionally, fishing gear used to target adult steelhead would be too large to catch juvenile spring chinook salmon, leading NMFS to determine that potential management actions and broodstock collection activities associated with the artificial propagation programs are not likely to adversely effect UCR spring chinook salmon.

4.1.3 Artificial Propagation Activities

The WDFW, the Chelan PUD, the Douglas PUD, the USFWS, and the Colville Tribes propose to operate artificial propagation enhancement programs for ESA-listed UCR steelhead. The *Biological Opinion on Artificial Propagation in the Columbia River* (NMFS 1999a) and the *Biological Opinion for 1995-1998 Hatchery Operations in the Columbia River Basin* (NMFS 1995) identify nine general types of potential adverse effects of hatchery operations and production on natural fish populations. These are: (1) operation of hatchery facilities, (2) broodstock collection, (3) genetic introgression, (4) density-dependent effects of hatchery production, (5) disease, (6) competition, (7) predation, (8) residualism, and (9) migration corridor/ocean. Adverse impacts on UCR spring chinook salmon resulting from UCR steelhead artificial propagation programs could only result from a few of the nine general types because of differences between the two species.

Physical operation of hatchery facilities impacts could occur from water withdrawal, release of hatchery effluent and facilities failure (NMFS 1999a). Water withdrawal for hatcheries located within the spawning and/or rearing areas can diminish stream flow from points of intake to outflow and, if great enough, can impede migration and affect spawning behavior. Effluent from the hatchery may change water temperature, pH, suspended solids, ammonia, organic nitrogen, total phosphorus, and chemical oxygen demand in the receiving stream's mixing zone (Kendra 1991).

Hatchery facilities operating to carry out the proposed programs rely largely on ground water withdrawal, although an important aspect of the two HCP agreements with Chelan PUD require the ability to hold steelhead adults and rear/acclimated juvenile steelhead on river water. Hatchery operators are required to comply with water right permits administered by Washington Department of Ecology established for each hatchery or acclimation site. This is intended to prevent over-appropriation of surface water needed for natural fish production and migration. Hatcheries facilities are also required to maintain all screens associated with water intakes in surface water areas to NMFS screening criteria (NMFS 1996). All hatcheries associated with the proposed action operate under NPDES permits that regulate water quality impacts. Reporting of hatchery effluent and water quality monitoring activities are part of the annual report to NMFS. Potential impacts of hatchery facility operation for the proposed programs were evaluated in an Environmental Assessment and determined to not be significant (NMFS 2003) . NMFS finds that adherence to water right limits, water quality NPDES permits, and NMFS screening criteria (NMFS 1996) are sufficient measures to protect the UCR spring chinook salmon ESU.

The release of steelhead smolts may cause displacement of rearing natural UCR spring chinook salmon from occupied stream areas, leading to abandonment of advantageous feeding areas or premature out-migration (Pearsons *et al*. 1994). The presence of large numbers of hatchery produced steelhead may also alter natural fish behavior patterns, which may increase their vulnerability to predation (NMFS 1995).

The release of only volitionally migrating smolts into the upper tributary reaches will contribute to a decrease in density-dependent effects on natural fish, by limiting interactions between natural and hatchery fish. Releases of hatchery smolts coincident with managed releases of water (flow augmentation) will also help accelerate downstream migration of artificially propagated steelhead, further reducing spatial and temporal overlaps with listed fish and potential adverse behavioral effects. When possible, release of juveniles which may residualize will occur into the lower tributary areas to minimize the potential adverse impacts on the naturally produced populations.

Artificially propagated steelhead smolts may prey upon other fish. Due to their location, size, and time of emergence, newly emerged chinook salmon fry are likely to be most vulnerable to predation by hatchery released fish. Their vulnerability is believed to be greatest as they emerge and decreases somewhat as they move into shallow, shoreline areas (USFWS 1994). Emigration out of release areas and foraging inefficiency of newly released smolts may minimize the degree of predation on chinook salmon fry (USFWS 1994).

Predation by artificially produced steelhead smolts on natural origin smolts is less likely to occur than predation on fry. The USFWS (1994) presented information indicating salmonid predators are generally thought to prey on fish approximately 1/3 or less their own length (see also Witty *et al.* (1995) citing Parkinson *et al.* (1989)). Consequently, predation by hatchery fish on listed salmon smolts in the migration corridor is believed to be low.

Large numbers of artificially propagated steelhead may attract predators (birds, fish, pinnipeds) and, consequently, contribute indirectly to predation of naturally produced fish. On the other hand, a mass of hatchery fish moving through an area may confuse or distract predators and may provide a beneficial effect to naturally produced fish. Both effects may be occurring to some extent. The presence of large numbers of hatchery fish may also alter the listed species' behavioral patterns, which may influence vulnerability and prey susceptibility (USFWS 1994). Considering the measures to protect UCR steelhead, the impacts of predation will not be substantial.

4.1.4 Research, Monitoring, and Evaluation

Research that may be conducted on artificially propagated UCR steelhead under the proposed permits will be evaluated by regional scientific and technical committees that have the responsibility to identify activities important for advancing the survival and recovery of ESA-listed anadromous fish populations. The three HCPs previously described require both HCP

Hatchery Committee and a HCP Coordinating Committee to address issues relating to programs funded by Chelan and Douglas PUDs. A representative of NMFS is on each committee. Federal and State agencies have the additional responsibility pursuant to their agencies mandates to protect and conserve the natural resources to coordinate research and monitoring actions with other co-managers that may or may not be represented on the HCP committees. This technical and scientific scrutiny is expected to ensure that research and monitoring activities that occur in the natural environment minimize adverse impacts on ESA-listed species while maximizing the survival and recovery of anadromous fish populations. Additionally, newly initiated research projects not considered in this Opinion will have to be evaluated for potential impacts to listed species pursuant to the ESA. The UCR steelhead program monitoring will likely over lap or be combined with UCR spring chinook salmon monitoring and provide a benefit to the UCR spring chinook salmon ESU.

The monitoring elements that are identified in this Opinion that may impact UCR spring chinook salmon are restricted to natural environment monitoring (Section 2.1.1.4.2). Natural environment monitoring of adult UCR steelhead includes redd and carcass surveys activities. Adult UCR spring chinook salmon spawn in August and September, while UCR steelhead spawn from January through May. This separation in spawn timing results in no impact on adult UCR spring chinook salmon. Juvenile UCR spring chinook salmon could be present in redds or occupying rearing habitat. Any impacts would be minor, transitory, and temporary.

Monitoring of juvenile UCR steelhead in the natural environment will be done using standard angling techniques and juvenile fish traps (i.e., rotary screw traps). These activities could encounter UCR spring chinook salmon. In previous years, no UCR spring chinook salmon have been encountered during sampling using standard angling techniques for residual UCR steelhead (Andrew Murdoch, WDFW personal communication, August 27, 2003).

The WDFW juvenile fish traps are generally operated to achieve a sample efficiency of four to 20 percent of the total brood production of the target species, depending on the river size. In the Wenatchee River basin, two juvenile fish traps are currently authorized under ESA permit 1203 to monitor natural production of UCR spring chinook salmon. In general, these traps result in mortality of less than two percent on target species and less than one percent on non-target species. In the Biological Opinion for permit 1203 (NMFS 1999b), the WDFW assumed mortality of listed UCR spring chinook salmon would not exceed three percent. Based on experience since that time, the WDFW has revised the mortality impact to be less than two percent on target species. The incidental mortality of UCR spring chinook salmon would not exceed one percent of the UCR spring chinook salmon captured. Using the larger of the two estimates of UCR basin natural production capacity for UCR spring chinook salmon of 753,168 smolts (Ford *et al.* 2001) and assuming trap efficiency of 20 percent and incidental mortality of one percent equals an impact of 1,506 smolts. Converting this to adult equivalents (1.3 percent survival smolt-to-adult, Ford *et al.* 2001) results in a maximum loss of up to 20 adult UCR spring chinook salmon. Considering that juvenile fish traps will likely not be operated in all tributary basins and not all traps will achieve an efficiency of 20 percent (for example the lower

Wenatchee River trap has previously achieved only about a two percent efficiency), the numeric impact will likely be much less and the impact to the ESU as whole is not substantial.

4.2 Effects on UCR Steelhead

Quantitative impacts estimated for the program on the natural population of UCR steelhead are provided below (Table 6 and Table 7), followed by a discussion of the relative effects of the numerical impacts. To address the potential impacts, the applicants propose minimization techniques and research, monitoring, and evaluation activities to assess the affects of the proposed programs, and a mechanism to adjust the programs consistent with the adaptive management approach adopted within the three HCPs. NMFS will place additional limits in the section 10(a)(1)(A) permits which will include facility operational sideboards, limits to the number of natural origin steelhead collected, and reporting requirements in order to reduce and monitor the direct take of UCR steelhead. Overall, the artificial propagation programs provide a benefit to the endangered UCR steelhead ESU by boosting the population abundance, while maintaining or increasing the genetic diversity, and spatial distribution.

Table 6. Estimated numerical or proportional non-lethal and lethal take of naturally produced and artificially propagated ESA-listed Upper Columbia River (UCR) steelhead adults.

Permit - Holder	Non-lethal	Lethal	Non-lethal	Lethal	Lethal Total

4.2.1 Adult Return Monitoring

The WDFW requests authorization to capture 10 percent of the annual steelhead run at Priest Rapids Dam for sampling. Biological sampling would include length measurements, collection of scales, visual examination for external marks and tags, and scanning with a coded-wire tag detector for presence of internal tags. The 10-year average run (1992-2001) is 10,383 steelhead, of which an average of 17.7 percent were naturally produced. Based on this average, about 1,038 steelhead total and about 184 naturally produced steelhead could be sampled annually. The range of natural-origin steelhead at Priest Rapids Dam is large (8.8 to 29.0 percent) and in some years could result in handling a higher proportion of natural-origin steelhead compared to the average. Previous sampling at Priest Rapids Dam has intercepted approximately 8-10 percent of the passing adult steelhead population (246 to735 adults; WDFW 1997). The potential benefit of this activity is the information which will allow for the active management of artificially produced steelhead on the spawning grounds, improved knowledge of the timing and distribution of natural and artificially propagated steelhead throughout the UCR basin which, combined with other data such as redd counts may be used to estimate the productivity of UCR steelhead. In the WDFW's and NMFS' judgement these benefits outweigh the potential adverse effects of collecting, handling, sampling, and releasing 10 percent of the run.

Radiotelemetry studies in 1999 and 2001 indicate a delay at Priest Rapids Dam of approximately 2.5 and 5.4 hours, respectively, when the trap is operated (English *et al*. 2001, 2003). Considering that the median travel time from Priest Rapids Dam tailrace to Wells Dam exit was 20.1 days in 1999 and 9.5 days in 2001, the few hours of delay for a small portion of the run is not substantial.

The WDFW indicates that no direct mortalities have been observed during the previous 16 years of sampling. The time from capture to release of steelhead at Priest Rapids Dam is generally less than five minutes, and after release above the trap into the fish ladder it is unlikely that delayed mortality steelhead would be observed. Groot *et al*. (1995) concede that the mechanisms connecting stress with disease induction in fishes are not fully understood. It is however, generally accepted that elevated plasma cortisol concentration caused by stress, is a key factor in increasing the susceptibility to disease. Water temperatures above the optimal range add an additional stressor. Optimal temperature range for steelhead is 45 to 58°F (7.2 to 14.4°C) (FPDEP 1991). In August through October, average daily Columbia River water temperatures at Priest Rapids Dam range between 52.8 and 69.2°F (11.6-20.7°C) (10-year average scroll case temperature from http://www.cqs.washington.edu/dart/dart.html, March 20, 2003) and 58 percent of the average daily temperatures are above the optimal range for steelhead (Figure 3). The experience level of samplers and the measures to reduce stress lead NMFS to assume that delayed mortality would not exceed one percent of the fish sampled during the warm water period. In an average run year, this would total 10 steelhead, 2 of which would be expected to be of natural origin.

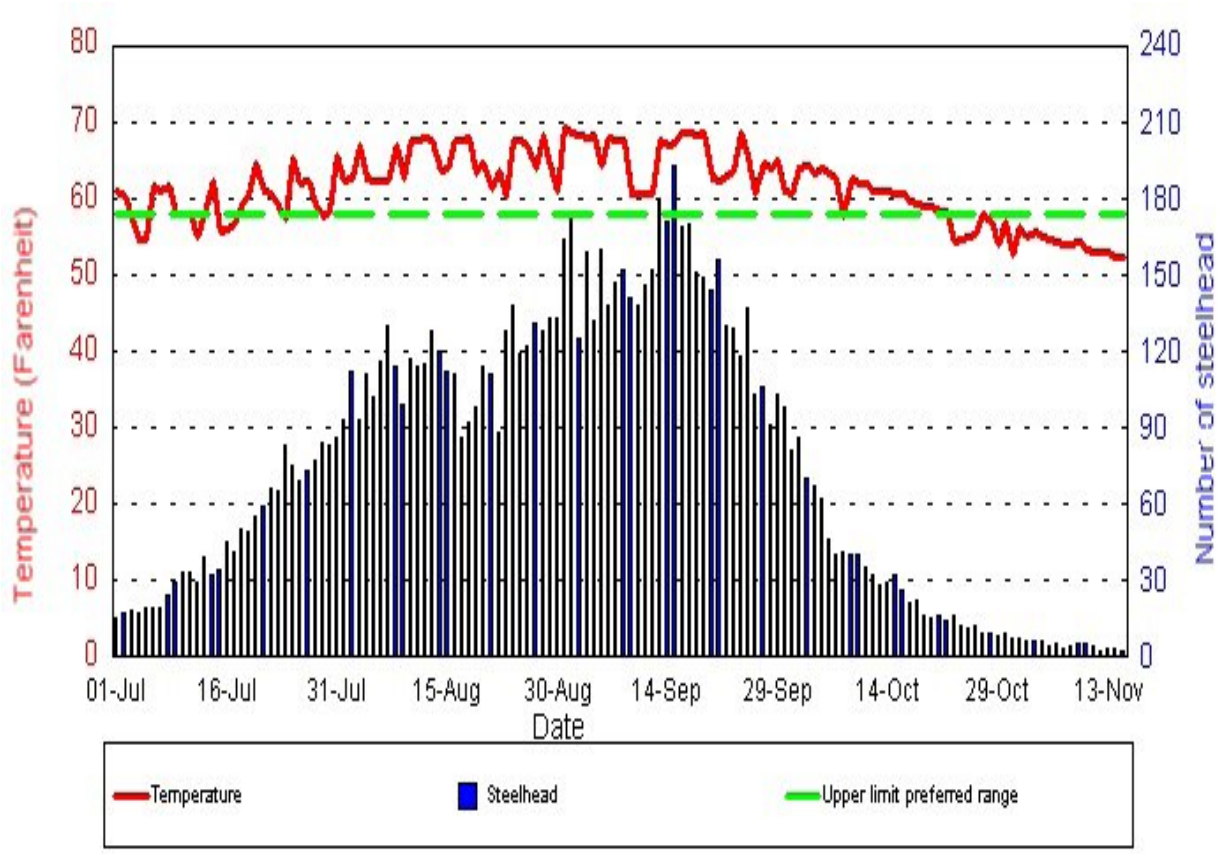

Figure 4. Ten year average upper optimal water temperature and daily passage of steelhead at Priest Rapids Dam.

The WDFW proposes to apply Petersen-type disk tags to the dorsal fin of adipose fin-clipped hatchery origin steelhead after September 9th in years where the run size is likely to exceed 1,300 natural origin steelhead and the total run is likely to exceed 9,550 steelhead. These run sizes are the initial triggers identified for considering additional actions such as recreational fisheries to manage returning hatchery origin steelhead. They reflect a minimum run that exceeds the 10-year average return of natural origin steelhead (years 1991 to 2000) and a starting point for recovery of the natural populations. The September 9th date is 21 days prior to October 1st, which is the earliest a recreational fishery would be opened. The anesthetic, tricaine methanesulfonate (sold under the brand names of Finquel or Tricane-S), commonly know as MS-222, used during sampling has a required 21-day withdrawal period set by the Food and Drug Administration, during which time the fish should not be available for human consumption.

The WDFW believes the application of this tag is necessary to identify steelhead that have been subjected to anesthetic to exclude them from harvest in a recreational fishery (see Section 4.2.2 below). The application of a Petersen disk tag involves the insertion of a wire that holds a 22mm diameter bright orange disk on both sides of the fish through the base of the dorsal fin. As

described above, the environmental conditions at Priest Rapids Dam are outside the optimal range for maintaining optimal steelhead health. The additional stress and injury of applying this type of tag could be expected to increase delayed mortality. Empirical data is lacking concerning the impacts of this specific activity on survival to spawning. The WDFW reports that steelhead with disk tags have been captured in recreational fisheries and that the tag and fish were both in good condition. No information on direct or delayed mortality resulting from application of this type of disk tag was found during a literature search. McFarlane *et al.* (1990) in their review of the development of external tags and marks summarized that this type of tag was first used in 1895 and continues to be a popular tag.

NMFS, based on the data cited above, concludes that the type of injury inflicted during the application of a disk tag is no greater than the injury sustained during hooking and releases steelhead in a recreational fishery under warm water conditions. Therefore, the delayed mortality would be expected to be no greater than 10 percent of the fish receiving a Petersen-disk tag. Run sizes exceeded the above triggers in nine of the last 17 (1978-2002) return years. Utilizing run sizes for those nine years and assuming that all artificially propagated steelhead smolts were adipose fin clipped NMFS calculated the following impact. Tag application would be limited to hatchery origin, adipose fin clipped steelhead, trapped after September 9th when, on average 62 percent of the run has passed Priest Rapids Dam (Figure 4), and only applied during relatively high run size years, on a portion of the fish sampled, the number of steelhead that would receive a disk tag would be about 485 and an estimated 49 steelhead would die. Currently, not all releases are adipose fin clipped and the number of tagged steelhead would be smaller than in this estimate. Since no adipose present natural-origin steelhead would be tagged, no impact to this component of the population would occur.

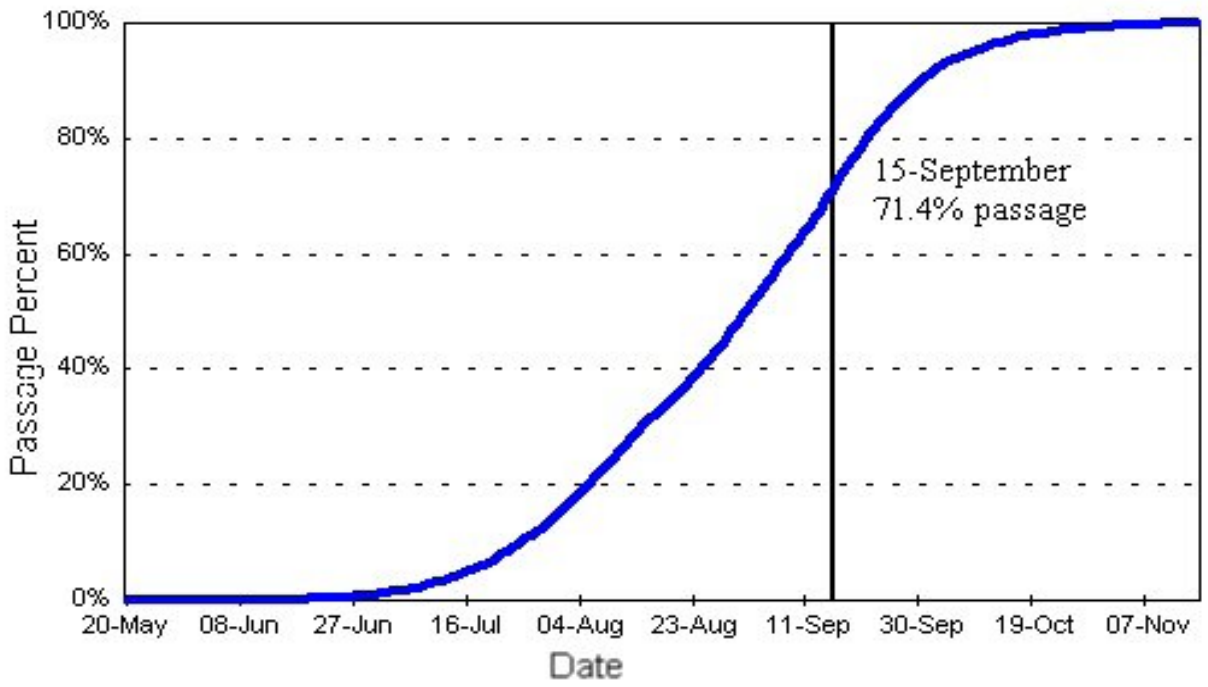

Figure 5. Ten year average cumulative run timing of steelhead at Priest Rapids Dam and the proposed September 15th date for adult steelhead management option assessment.

Additionally, the WDFW proposes to radio/active tag or up to 400 steelhead at Priest Rapids Dam in some years. Radio/active tags would be used to assess migration timing, route, survival, as well as tributary migration and spawning distribution. Radio tag studies conducted by the PUDs have indicated that stray rates of artificially propagated steelhead are higher than expected (English *et al*. 2001, 2003). Considering the current uniformity of the Wenatchee and Wells steelhead stocks in terms of both genetic identity and hatchery program management the stray rates are not entirely surprising. Radio tagged steelhead have been captured and retained during broodstock collection activities. In NMFS' judgement, in years when radio/active tracking is conducted in tributary areas that it would be beneficial to leave radio/active tagged steelhead in the natural environment to collect information on spawning distribution, timing and kelting. Additionally, some radio/active tagged steelhead have been harvested during recreational fisheries; again; potential spawning information is lost when radio/active tagged steelhead are removed from the river. As the tributary oriented programs continue to develop, radio/active tag studies will likely be a very useful measurement tool to determine if tributary oriented artificial propagation strategies are effective. Prior to initiating a radio/active tag study for a given year, the HCP Hatchery Committees will review and approve the study design. Delayed mortality that result of radio/active tagging is assumed to occur at a rate of about 5 percent. Therefore, the ten-year average run size mortality from the telemetry study would be about 20 steelhead, of which only about 20 percent would be of natural origin, resulting in a mortality estimate of four natural origin steelhead.

The cumulative effects of the basic stock assessment activities, and the additional application of a disk tag, and/or a radio/active tag would be expected to result in some occurrence of delayed mortality. A steelhead run consistent with the 1978-2002 average run and all activities occurring would result in a capture, handling, tagging and release mortality impact range of about six natural origin and 48 artificially propagated steelhead. Take in the form of capture, handle, release will not exceed 10 percent of the total run, with mortality from the take not expected to exceed one percent. Take from these monitoring and evaluation activities is not expected to exceed 3.8 percent of the total run and mortality is not expected to exceed 0.2 percent of the total run. This mortality would be limited to years of high returns of both natural and artificially propagated steelhead. In an average run, the take is equal to about 20 steelhead, of which 4 fish (20 percent) would be of natural origin. Given that the average run size is 13,306 (1978 to 2002), the total potential loss of 20 steelhead, predominately artificially propagated steelhead is not a substantial impact considering the potential benefit of the data collection. The data collected is potentially very valuable for future recovery and management actions in the UCR basin as well as other salmon and steelhead populations.

In order to minimize the potential impacts on UCR steelhead from the monitoring activities, the WDFW proposes specific trap operation and fish handling measures adherence to which will be a condition of the permit (see Section 2.2.1.1). NMFS finds these measures are adequate to minimize the adverse impacts on ESA-listed UCR steelhead and that these activities provide a net benefit to the recovery of ESA-listed steelhead in the UCR basin.

4.2.2 Adult Return Management

The ESA intends to ensure the protection and restoration of species in their native habitats. In some years the return of adult UCR steelhead is higher than what is needed to fully seed the habitat which is not surprising since much of the artificial propagation program is produced as mitigation for inundation of habitat. Priority in conservation is afforded to naturally produced steelhead to ensure the highest potential for successful natural production. NMFS in the ESU determination has recognized that the artificially produced steelhead in the UCR are an important component of the recovery effort. However, in years of high survival and return of naturally produced steelhead, the individuals that were the products of the natural environment should be given priority to spawn naturally to perpetuate the species. In years of large returns of artificially produced steelhead to the UCR, the WDFW seeks to reduce the potential negative effects of excess artificially propagated escapement by several methods.

The WDFW proposes to purposefully manage artificially propagated UCR steelhead adults returning to the UCR basin to provide adequate escapement to fully seed the spawning habitat. Artificially produced steelhead have been an important component of the spawning escapements to the Wenatchee and Methow basins. Recent hatchery reforms and recovery strategies include the development of a Wenatchee basin steelhead stock and incorporation of naturally produced adults into the hatchery programs in both basins. Please see the WDFW application for a full

discussion of hatchery program strategies (WDFW 2002). Below are brief descriptions of the different strategies that WDFW will use to manage UCR adult hatchery steelhead.

The Ringold Springs steelhead program serves several purposes. First it provides a genetic reserve for the UCR steelhead ESU in case of catastrophic crash of the upper basin population. Second, it allows managers to remove the earliest spawning component of the Wells Hatchery stock which historically was artificially selected for by well intentioned hatchery managers. This action is one hatchery reform measure intended to help reverse previous adverse impacts of hatchery program management. It provides these benefits to the recovery of the population and an additional benefit of recreational angling in an area that has minimal adverse impacts on the natural steelhead populations. The WDFW proposal to open recreational harvest fisheries in the area adjacent to Ringold Springs would be expected to remove excess artificially propagated steelhead and result in the hook and release of few natural origin steelhead.

In areas above Priest Rapids Dam, several methods have been used to estimate the number of steelhead spawners and juveniles that the available habitat may be capable of supporting. These estimates for the UCR basin range from 1,603 to 8,281 depending on the estimation method (Ford *et al*. 2001). The Interior Columbia Basin Technical Recovery Team (TRT) is reviewing the available data and is expected to provide escapement recommendations for recovery of all ESA-listed UCR species. The WDFW proposes to manage artificially propagated steelhead at levels above the interim abundance targets developed by NMFS (Lohn 2002) until the TRT recommendations are available. NMFS has not developed abundance targets for the Okanogan basin or other smaller tributaries. The WDFW proposes abundance levels for these tributaries for management purposes as well (Table 8).

Table 8. Interim abundance targets of naturally produced steelhead by basin and approximate natural origin broodstock collection goal.

Basin	Interim Abundance Target	Broodstock Goal
Wenatchee	2,500	at least 104 [a]
Entiat	500	- -
Methow	2,500	maximum 123 [b]
Okanogan	600	16
Small Tributaries	200	- -
Total	**6,300**	**243**

[a] *Proportional to run-at-large in years when run is composition is 50% or greater natural origin steelhead, otherwise goal is 50% naturally produced steelhead. Total broodstock collection goal is generally about 208 steelhead..*

[b] *Combined WDFW Methow/Okanogan programs will not exceed 30% natural origin steelhead in the broodstock. Up to 373 steelhead may be collected for broodstock total.*

Artificially produced steelhead released into the UCR basin have three potential parental backgrounds: two natural origin parents, two hatchery origin parents, or one parent of each.

Currently artificially propagated steelhead are externally marked either with a uniquely colored visual implant elastomer (VIE) tag behind the eye or by removing the adipose fin. Artificially propagated steelhead may also receive internal tags such as coded-wire tags or passive integrated transponder (PIT) tags. Based on these marks and tags observed during adult monitoring at Priest Rapids Dam, the WDFW proposes to estimate the composition of the run, including the proportion of natural origin steelhead, and the proportions of artificially propagated steelhead by release location, release group, and parental background. This information will be used to determine if actions to manipulate the proportion of hatchery steelhead in each of the populations in the Wenatchee, Methow, and Okanogan river basins to improve the potential for successful reproduction of naturally produced steelhead are appropriate for a given year.

Utilizing several methods, the WDFW proposes to manage adult steelhead returns to increase the proportion of natural origin steelhead in the spawning populations in each tributary basin. One method is to remove steelhead at trap sites such as the Wells Dam ladders, Ringold Springs ladder, hatchery traps and fishways. Collected hatchery steelhead can then be transported to landlocked lakes for subsequent recreational harvest opportunities. The WDFW believe the stress to individual steelhead being removed will be no more than what currently occurs when steelhead are captured, examined, and released during the currently-authorized activities (WDFW 2002).

Artificially propagated steelhead surplus to program objective can also be removed through recreational harvest, and the WDFW includes this in their proposal. The WDFW summarize that the literature concerning mortality of adult steelhead following release by trout anglers occurs at a rate of less than 5 percent. The WDFW reports (WDFW 2002) that hooking mortality on natural steelhead adults caught during winter conditions (in cool [<50°F] water), including those caught with bait, sustain a hooking mortality of 1.1 percent, while year-round fisheries sustained a hooking mortality of 3.7 percent. The WDFW assumes a 5 percent mortality for adult steelhead caught in UCR fisheries from September through March. Columbia River temperature at Wells Dam in September exceeds 58°F until November 2nd (10-year average, http://www.fpc.org/). Most angling is expected to occur in the tributary areas and after water temperature begins to decrease.

NMFS proposes take limits, specifically mortality limits, based on the natural origin UCR steelhead tributary population escapement to spawning. These limits are defined in Table 10 and assume a catch and release mortality rate of 5 percent. The potential adverse impact in the form of dead natural origin UCR steelhead ranges from 2 to 10 percent of the natural origin steelhead in each tributary spawning area (Table 9) depending on the natural origin UCR steelhead run size and total (natural plus hatchery) run size.

Table 9. Proportional natural-origin UCR steelhead mortality take limit for recreational harvest fisheries in the Wenatchee River, Methow River, and Okanogan River basin tributary areas by run size. Catch and release mortality is assumed to be five percent.

Tributary Area	Priest Rapids Dam Count	Escapement to Tributary Area	Mortality Impact	
			Proportion	Count
Wenatchee River and Columbia River above Rock Island Dam to below Rocky Reach Dam				
	<837	<599	0%	0
Tier 1	838	600	2%	12
Tier 2	2,146	1,700	4%	68
Tier 3	3,098	2,500	6%	150
Methow River and Columbia River above Wells Dam				
	<803	<499	0%	0
Tier 1	804	500	2%	10
Tier 2	2,224	1,600	4%	68
Tier 3	3,386	2,500	6%	150
Okanogan Basin upstream of the Highway 97 Bridge				
	<175	<119	0%	0
Tier 1	176	120	5%	6
Tier 2	180	120	7%	8
Tier 3	795	600	10%	60

The constraints on the impact are designed such that the highest risk is taken in the Okanogan River basin which has been identified as having the least suitable spawning and rearing habitat for steelhead and less risk in the Methow and Wenatchee River basins. Also, no interim abundance target has been define by NMFS for this basin. When the minimum natural origin run size at Priest Rapids Dam of 1,300 steelhead is met, and the tributary run size criteria are met in a particular basin, recreational fisheries could occur in each basin which meets the criteria. For example at the minimum Priest Rapids Dam run size of 1,300, it is not possible to meet the 176 Okanogan basin level and both minimum criteria in the Methow and Wenatchee river basins because the secondary tributary criteria could not be met (838+804+176=1,818). Take limits increase as progress toward recovery is made in the form of increasing natural origin UCR steelhead run sizes. At the minimum Tier 1 criteria, the proportional mortality limit is two percent in the Wenatchee River area or Methow River area and could result in the loss of up to ten or 12 natural origin steelhead from the spawning population in the Methow or Wenatchee basin and up to six natural origin UCR steelhead from the Okanogan River basin. At the maximum end of Tier 1 impacts - 1,699 natural origin steelhead returning to the Wenatchee River and 1,599 returning to the Methow River basin for spawning, which would require at total

natural origin steelhead run of 4,415, fisheries could occur in both basins and a two percent impact would result in up to 34 and 32 natural origin steelhead adults being killed in the Wenatchee and Methow River basins, respectively. At Tier 3 criteria levels the tributary populations have met the currently identified interim abundance targets and the risks associated with the loss of relatively few natural origin steelhead is not substantial. Under this two criteria strategy (Priest Rapids Dam run size and tributary escapement size), if recovery in the Wenatchee and Methow River basins is disproportionate, that is one basin approaches recovery levels of natural origin steelhead and a much greater rate than the other, recreational fisheries could occur in each basin at different impact levels.

Additionally, the WDFW proposes to employ the following measures to minimize the potential adverse impacts of these activities on natural origin UCR steelhead. These will be included as additional conditions in the permit:

- The mandatory release of all adipose fin-present steelhead;
- Fishery openings are established to protect important spawning and outmigration periods;
- Fisheries are selective for adipose fin-clipped or otherwise externally marked hatchery origin steelhead;
- Selective gear regulations will be in effect for fisheries authorized in the tributaries;
- Sanctuary areas in the tributary basins will be established and maintained to protect important production areas;
- Provide information on natural origin fish release requirements and selective gear regulations in the annual Washington Sport Fishing Rules pamphlet, in periodic media news releases, and with signs posted in the fishing areas;
- The WDFW Enforcement Program will enforce these regulations by conducting periodic random and special emphasis patrols;
- Managers must have assurance that the abundance of returning adult UCR steelhead is sufficiently high to meet escapement objectives and achieve hatchery broodstock goals before fisheries will occur.

Benefits to removing excess artificially produces UCR steelhead include increasing the proportion of natural origin steelhead on the spawning grounds. This also reduces the genetic risks to natural populations such as swamping, masking, and density dependant effects created when the habitat is fully seeded and an over abundance of hatchery reared steelhead are on the spawning grounds. NMFS finds that once the minimum UCR steelhead abundance criteria are met, that the benefits of removing surplus artificially propagated UCR steelhead outweigh the small numeric reduction of natural origin UCR steelhead of the recreational fisheries.

4.2.3 Artificial Propagation Activities

The WDFW, Chelan PUD, Douglas PUD, USFWS, and Colville Tribes propose to operate artificial propagation enhancement programs for ESA-listed UCR steelhead. The *Biological Opinion on Artificial Propagation in the Columbia River* (NMFS 1999a) and the *Biological Opinion for 1995-1998 Hatchery Operations in the Columbia River Basin* (NMFS 1995) identify nine general types of potential adverse effects of hatchery operations and production on natural fish populations. These are: (1) operation of hatchery facilities, (2) broodstock collection, (3) genetic introgression, (4) density-dependent effects of hatchery production, (5) disease, (6) competition, (7) predation, (8) residualism, and (9) migration corridor/ocean.

The take of endangered UCR steelhead requested by the applicants will result from proposed artificial propagation enhancement programs designed to benefit ESA-listed UCR steelhead. The primary objectives of these efforts are to preserve extant steelhead populations in the region, and to boost the abundance of remaining stocks. There are risks of ecological and genetic impacts on the ESA-listed juvenile and adult steelhead resulting from the proposed programs. However, the risk of extinction to natural populations is high enough that aggressive intervention is proposed. Strategies are proposed to minimize potential impacts on endangered steelhead that may be associated with these programs.

4.2.3.1 Operation of Hatchery Facilities

Potential adverse impacts identified with the physical operation of hatchery facilities include impacts from water withdrawal, release of hatchery effluent and facilities failure (NMFS 1999a). Hatchery effluent may transport pathogens (disease) out of the hatchery and infect natural-origin fish. Aside from the potential impacts on water flow and quality, operational failures due to power/water loss, flooding, freezing, vandalism, predation and disease may result in catastrophic losses to rearing adults and juveniles.

Flow reductions, flooding and poor fish culture practices may all cause hatchery facility failure or the catastrophic loss of listed fish under propagation. To protect endangered steelhead, all efforts should be made to ensure that the survival of adult steelhead held for broodstock at the hatchery facility be maximized. The applicants propose a variety of measures to address risks associated with operational failures, including:

- Protection of fish from vandalism and predation is provided by fencing, locks, and security lights at all hatchery facilities;
- Rapid response in the event of power and water loss or freezing is provided by a combination of staffing and automated alarm paging systems;
- Equipping hatchery facilities to ensure reliable power to provide water to rearing fish during power outages;

- Rearing juveniles at lower pond loading densities to minimize the risk of loss due to disease; and
- Ensuring staff are adequately trained in proper fish handling, rearing, and biological sampling techniques, and that all activities will be conducted in accordance with the WDFW Fish Health Manual (WDFW 1996) and/or Pacific Northwest Fish Health Protection Committee (PNFHPC 1989) disease prevention and control standards.

NMFS finds operational measures proposed which will be included as additional terms and conditions in the permit will adequately protect ESA-listed UCR chinook salmon and UCR steelhead. The proposed measures are in accordance with standard scientific protocols for operating hatchery facilities (IHOT 1995). Further, staff implementing these programs will be sufficiently trained and will be qualified to exercise professional judgement should unforeseen circumstances arise.

4.2.3.2 Broodstock Collection

Broodstock collection typically involves a weir or barrier that forces migrating adults to enter a ladder and trap. This effectively blocks their upstream migration and the trapped steelhead are counted and either retained for use in the hatchery or released upstream of the collection facility to continue their migration and spawn naturally. Potential adverse effects to adults include delaying upstream migration, rejection of the weir or fishway structure resulting spawning downstream of the trap, falling back downstream after passing upstream of the collection facility, being injured or killed as adults attempt to jump the barrier, and inducing stress by handling. These impacts are due to the physical presence and operation of the trap, other potential impacts of broodstock collection including the numerical reduction of the donor population (mining), and selection effects.

Collection of steelhead for broodstock will occur at various dams, hatchery ladders, or using temporary weirs. Hook and line capture of broodstock may be used in some years if other methods are not successful in collecting steelhead. When in operation, trap facilities will be checked and emptied daily with adults to be used as broodstock transported to a hatchery facility for holding and spawning, and all other fish released upstream of the trap. Direct mortality from broodstock collection activities has been low (WDFW 1997). Hook and line collection of broodstock is the least preferred technique that would be employed when other collection options had been thoroughly considered. Handling stress of adult steelhead captured by hook and line will be minimized.

The proposed actions include the development of annual site-based broodstock collection protocols by the Hatchery Committee as described in the three HCPs. A representative from NMFS is on each of the HCP Hatchery Committees to ensure the collection protocols employed will not be detrimental to the persistence and recovery of ESA-listed species. The objectives and protocols may be adjusted in season to meet changes in the abundance and location of adult

returns, and minimizing impacts on non-target fish. The total broodstock collection will not exceed 208 steelhead in the Wenatchee basin and 389 for areas above Wells Dam.

Historically, the trapping of adult steelhead for broodstock in the Wenatchee River generally occurs from July to November at Dryden and Tumwater Dams. Both of these facilities may be operated for concurrent broodstock collections of non-ESA-listed species (summer chinook salmon, sockeye salmon, or coho salmon) consistent with ESA permit 1347 and section 7 consultation with BOR. Dryden Dam was specifically engineered to intercept less that 100% of the migrating adult salmonids. In years of very low run sizes broodstock collection of steelhead can be problematic. Therefore, hook and line collection of steelhead adults may be necessary in those years of low returns. Utilization of these trapping locations is for the purpose of developing a locally-adapted broodstock for the Wenatchee River basin. Historically, all steelhead releases into the Wenatchee River were offspring of steelhead collected at Wells Dam and Wells Hatchery. However, since 1996 steelhead broodstock for the Wenatchee basin have been collected from these facilities.

The WDFW and Colville Tribes will employ the following procedures to minimize potential adverse impacts on salmon and steelhead associated with broodstock collection activities:

- All species will be held for a minimal duration in the traps – less than 24 hours;
- Traps and holding areas will be locked or secured against tampering or vandalism;
- All species including steelhead in excess of broodstock goals will be released upstream immediately without harm;
- Steelhead transfers will be done using water-to-water techniques;
- Hook and line technique will be last collection option employed.

The removal of adults from the naturally spawning population has potential adverse impacts. These include numerical reduction of the natural population (mining) and selection effects. Selection is the intentional and unintentional collection of adults for broodstock based on one or more of the life history characteristics such as run timing, age, morphology and sex ratio, that do not fully represent the natural (or target) population. The effects of selection or selection effects can change the characteristics of the natural population as well as cause the hatchery-produced fish to diverge genetically or demographically from the naturally produced population.

The proposed supplementation program is designed to preserve and rebuild naturally producing steelhead populations in the UCR Region. Natural steelhead in the UCR ESU are not replacing themselves and extinction appears likely without the proposed program. Risks to the donor natural populations, including numerical reduction and selection effects, are therefore viewed by the permit applicants and NMFS as subordinate to the need to expeditiously implement the supplementation program that will prevent extinction of the ESU (BAMP 1998). To preserve the

remaining natural populations and to address the numerical reduction and selection effects the following measures will be implemented and included in the permit additional conditions:

- Broodstock removals will be limited to a maximum of 104 natural origin steelhead from the Wenatchee basin and 289 for areas above Wells Dam; and
- Removal of adult broodstock at traps for the enhancement programs shall be consider the composition of the run-at-large with respect to migration timing, age class, and morphology, collection decisions made to maximize the natural population recovery efforts.

NMFS finds that the proposed broodstock collection strategies and that the numerical collection limits will protect naturally produced ESA-listed UCR steelhead.

4.2.3.3 Genetic Introgression

Hatchery fish straying into UCR steelhead natural production areas can potentially lead to long-term deleterious effects on natural steelhead populations. The genetic risks to natural populations from hatchery propagation include loss of fitness, reduction in genetic variability within and between populations, genetic drift, selection and domestication (Hard *et al.* 1992; Cuenco *et al.* 1993; NRC 1996; and Waples 1996). Because of these risks, it is recommended that straying of hatchery fish be minimized to reduce the effects of genetic introgression on natural populations (Hard *et al.* 1994). Campton (1995) provides a discussion of what is known about the genetic effects of hatchery reared fish on natural populations and concludes that most of the observed or suspected effects are due to management decisions rather than biological factors intrinsic to hatcheries or hatchery fish.

It is likely that UCR steelhead have been adversely impacted by previous management actions concerning artificial propagation programs. Substantial genetic mixing of populations within this ESU has occurred from fish being stocked into non-local sub-basins as a result of the Grand Coulee Fish Maintenance Project and from the Wells Hatchery steelhead program. The proposed actions may continue to adversely affect natural steelhead in the future if the number of hatchery fish straying into natural steelhead production areas is in excess of the desired number and/or development of locally-adapted broodstock is not accomplished in the tributary basins.

Historically, steelhead broodstock have been held on pathogen free well water which is warmer than river water. This combined with historic selection of the earliest maturing component of the run has resulted in the acceleration of sexual maturation. Due to this developmental acceleration, hatchery fish spawn from January through March whereas natural fish spawn in April and May. During the previous few years hormone treatment of natural-origin steelhead broodstock and experiments with artificial light have been used in attempts to align the maturation schedules of both hatchery and natural origin steelhead. In addition, the eggs from the earliest spawning hatchery origin steelhead have been utilized in the Ringold Springs program. This action is intended to be one step toward correcting previous hatchery management actions that likely had

an adverse impact on the natural population. Radio telemetry data in 2001-2002 indicate that some of the steelhead released into the Columbia River from the Ringold Springs program migrate back to the UCR area. In order to limit this straying, the Ringold Springs program should be maintained at the 200,000 smolt release level until monitoring indicate that the fish are no longer straying upstream and posing an increased risk to the recovery efforts.

In the two HCP agreements with Chelan PUD there is a requirement that the hatcheries have the ability to hold Wenatchee steelhead broodstock on river water. This measure is one step toward creating the best environment for holding maturing adult UCR steelhead.

Additionally, the long term strategy for steelhead artificial propagation programs in the UCR includes limiting the percentage of hatchery reared steelhead on the spawning grounds following achievement of recovery goals. NMFS expects the resource managers to take steps to reduce the potential adverse impacts on the natural reproducing population such as altering release locations to modify adult return behavior and modifying external marking strategies of juveniles released to increase management options for removal of excess adult steelhead. NMFS at this time includes a long term target of no more than 20 percent of the spawners being of hatchery origin in the Wenatchee River and Methow River basins and no more than 50 percent in the Okanogan River basin once recovery goals are achieved (Figure 5 and Figure 6).

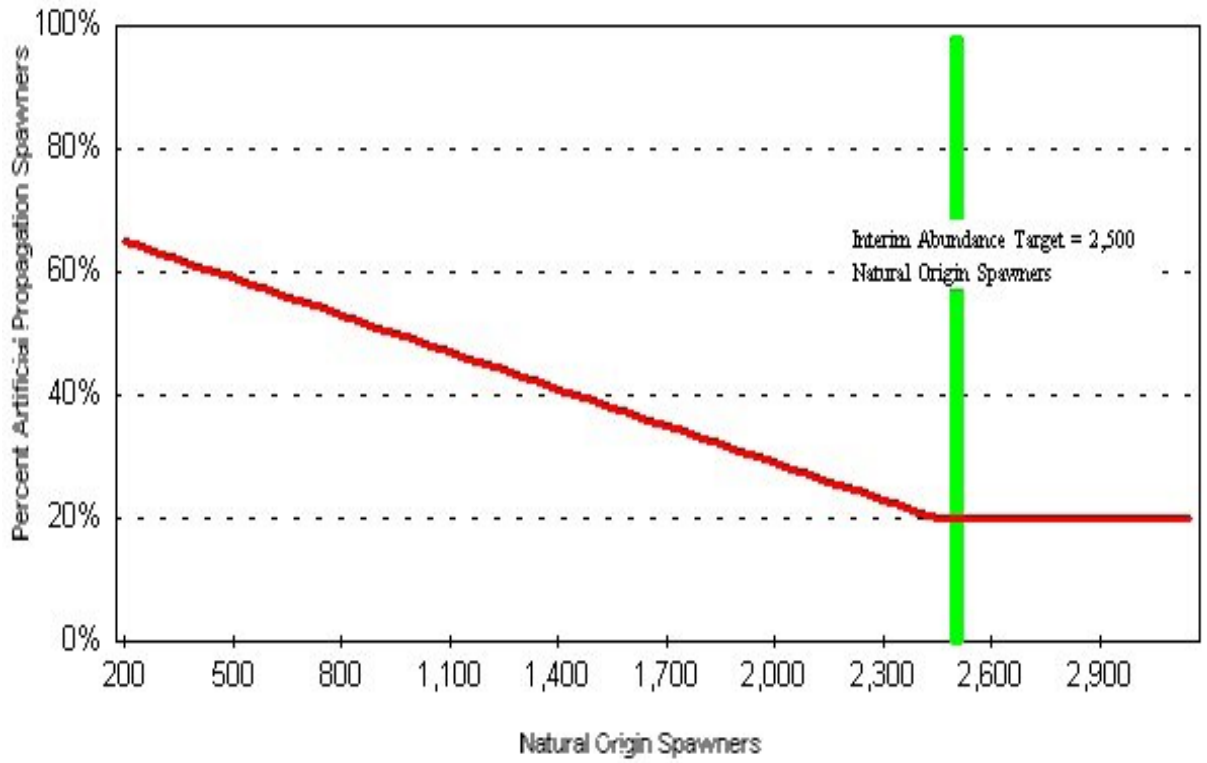

Figure 6. Wenatchee and Methow River Basin management objective for limiting artificially propagated steelhead on spawning grounds as natural origin steelhead population increases.

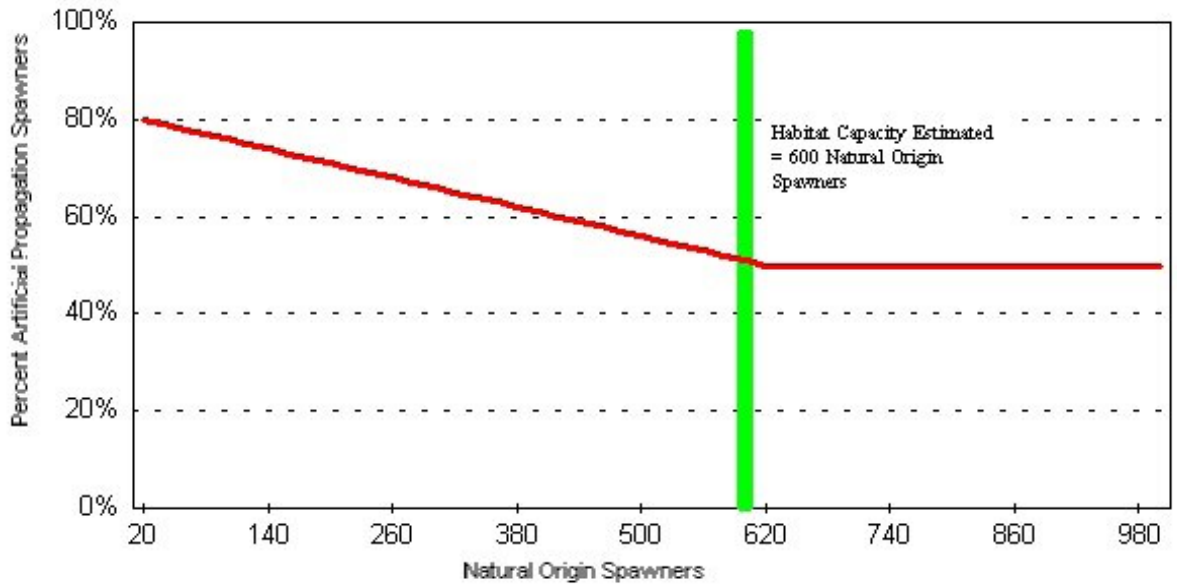

Figure 7. Okanogan Basin management objective for limiting artificially produced steelhead on spawning grounds as natural origin steelhead populations increase.

4.2.3.4 Density-Dependent Effects

Steelhead smolt releases may cause displacement of rearing natural steelhead juveniles from occupied stream areas, leading to abandonment of advantageous feeding areas or premature out-migration (Pearsons *et al*. 1994). The presence of large numbers of newly released steelhead may also alter natural fish behavior patterns, which may increase their vulnerability to predation (NMFS 1995).

The release of only volitionally migrating smolts into the upper tributary reaches will contribute to a decrease in density-dependent effects on natural fish, by limiting interactions between natural and hatchery fish. Releases of smolts coincident with managed releases of water (flow augmentation) will also help accelerate downstream migration of artificially propagated steelhead, further reducing spatial and temporal overlaps with listed fish and potential adverse behavioral effects. Release of juveniles that have an increased tendency to residualize into the lower tributary areas, when possible, will minimize the potential adverse impacts on the naturally produced populations.

4.2.3.5 Disease

Interactions between hatchery fish and listed fish in the natural environment may be a source of pathogen transmission. This impact is probably occurring in headwater spawning and/or rearing areas and throughout the entire migration corridor. Because the pathogens responsible for diseases are present in both hatchery and natural-origin populations, there is some uncertainty associated with determining the extent of disease transmission from hatchery fish (Williams and Amend 1976; Håstein and Lindstad 1991). However, hatchery populations are potential reservoirs of disease pathogens because of the high rearing densities and resultant stress. Under natural conditions, which usually involve rearing at low density, most pathogens are held in check. When an epizootic event occurs, it is often triggered by increased population density and unusual changes in the environment (Saunders 1991). Consequently, it may be possible that release of large numbers of smolts may be responsible for some loss of natural steelhead from disease.

Although hatchery populations can be reservoirs for disease pathogens because of their elevated exposure to high rearing densities and stress, there is little evidence to suggest that diseases are routinely transmitted from hatchery to natural fish (Steward and Bjornn 1990). Chapman et al. (1994) concluded that disease transmittal from hatchery to natural populations is likely not a major factor negatively affecting natural steelhead in the Columbia basin.

To address concerns of potential disease transmission from hatchery to natural fish, the Pacific Northwest Fish Health Protection Committee (PNFHPC) has established guidelines to ensure hatchery fish are released in good condition, thus minimizing impacts on natural fish (PNFHPC 1989). Also, the IHOT (1995) developed detailed hatchery practices and operations designed to prevent the introduction and/or spread of any fish diseases with the Columbia River basin. Hatchery facility operators in the UCR basin follow fish health protocols in accordance with PNFHPC and IHOT recommended guidelines.

The WDFW, USFWS, and Colville Tribes will implement both disease prevention and disease control techniques to maximize production of healthy fish. Spawned adults are evaluated for the presence of viral and bacterial pathogens following accepted standard procedures set forth by the Salmonid Disease Control Policy of the Fisheries Co-managers of Washing State (NWIFC and WDFW 1998 and the Pacific Northwest Fish Health Protection Committee (PNFHPC 1989). NMFS finds that following these practices in the hatchery environment will adequately protect listed naturally produced UCR steelhead from impacts from the transmission of disease.

4.2.3.6 Competition

Direct competition for food and space between artificially propagated and naturally produced fish may occur in spawning and/or rearing areas, the migration corridor, and ocean habitat. These impacts are assumed to be greatest in the spawning and nursery areas and at points of highest fish density (release areas) and to diminish as hatchery smolts disperse (USFWS 1994). Competition

continues to occur at some unknown, but probably lower, level as smolts move downstream through the migration corridor. Release of large numbers of pre-smolts in a small area is believed to have greater potential for competitive effects because of the extended period of interaction between hatchery fish and listed species. Release of smolts that are physiologically ready to migrate is expected to minimize competitive interactions because they are more likely to quickly migrate out of the spawning and nursery areas.

When artificially propagated steelhead smolts are released into the UCR basin, a potential exists for inter-specific competition with naturally produced steelhead. These effects are likely to be greatest near the point of release and decrease as the smolts disperse and migrate seaward. Release of artificially propagated steelhead may adversely impact natural steelhead especially if hatchery fish are larger and food and space are limited. However, competition should be minimized because only smolts demonstrating migratory behavior and/or smolting characteristics will be released. In most years, releases will be scatter planted to reduce instantaneous densities of hatchery fish in natural production areas (WDFW 1997). Monitoring of residualization is provided for in Section 2.2.1.3 (Research, Monitoring, and Evaluation).

Competition for prime spawning habitat could occur in years of high survival to adult of both natural and artificially produced steelhead. As recovery plans are implemented, the number of natural origin steelhead should increase. The utilization of artificially propagated steelhead to supplement natural spawning should be reduced as natural populations rebound. NMFS has identified an approximate long-term management sliding scale to assist hatchery managers to make appropriate decisions concerning release strategies of artificially propagated steelhead smolts. As the number of natural origin spawners increases the number of hatchery reared smolts released high in tributary systems should decrease to reduce the potential for competition and genetic swamping of the natural population. Artificially propagated steelhead could then maintain recreational harvest opportunities particularly in lower tributary areas without posing substantial risk to the UCR steelhead ESU.

4.2.3.7 Predation

Predation by hatchery fish on natural-origin smolts is less likely to occur than predation on fry. The USFWS (1994) presented information indicating salmonid predators are generally thought to prey on fish approximately 1/3 or less their own length (see also Witty *et al.* (1995) citing Parkinson *et al.* (1989)). Consequently, predation by hatchery fish on listed salmon smolts in the migration corridor is believed to be low.

Large numbers of artificially propagated steelhead may attract predators (birds, fish, pinnipeds) and, consequently, contribute indirectly to predation of naturally produced fish. On the other hand, a mass of hatchery fish moving through an area may confuse or distract predators and may provide a beneficial effect to naturally produced fish. Both effects may be occurring to some extent. The presence of large numbers of hatchery fish may also alter the listed species' behavioral patterns, which may influence vulnerability and prey susceptibility (USFWS 1994).

Impacts from predation by hatchery-produced steelhead released into the UCR are not likely to be a substantial risk to ESA-listed naturally produced UCR steelhead because of their size at release and because they tend to migrate out of the basin quickly.

4.2.3.8 Residualism

Artificially propagated steelhead have the potential to residualize after release in the freshwater environment. The degree of residualism can vary greatly, but is thought to typically average between 5 and 10 percent of the number of fish released (USFWS 1994). Hatchery steelhead residuals can compete for food and space, prey upon, and/or transfer disease to other salmonids.

Volitional or scatter planted release strategies will be used to reduce the residualization of hatchery fish. In addition, acclimation sites are currently being researched and developed. These techniques help promote rapid downstream migration of released smolts and reduce interactions of hatchery and natural fish. The WDFW is proposing to release only juvenile steelhead with demonstrated readiness for seaward migration into the upper tributary areas where feasible. Smolt releases will also be timed with water budget releases from upstream dams to further accelerate rapid downstream movement (WDFW 1997). Investigations of the propensity and the causes of residualism of artificially propagated steelhead will be part of the research, monitoring, and evaluation program developed by the HCP Hatcheries Committees (see Section 4.2.4). When monitoring indicates that a hatchery population may have a tendency to residualize at a higher than expected rate, the group will be released into lower tributary areas or hatchery management changes will be implemented.

4.2.3.9 Migration Corridor/Ocean

Considerable speculation, but little scientific information, is available concerning the overall effects to listed salmon and steelhead from the combined number of hatchery fish in the Snake/Columbia River migration corridor. In a review of the literature, Steward and Bjornn (1990) indicated that some biologists consider density-dependent mortality during freshwater migration to be negligible; however, they also cited a steelhead study that indicated there may have been a density-dependent effect (Royal 1972, cited in Steward and Bjornn 1990). Hatchery and natural populations have similar ecological requirements and can potentially be competitors where critical resources are in short supply (LGMSC 1993).

A total of about 1.1 million steelhead smolts will be released into the Wenatchee, Methow and Okanogan River basins. The artificial propagation programs will be managed to produce only juvenile steelhead ready for seaward migration. Proposed maximum production for these facilities is the same as when the Columbia basin annual production ceiling was established in 1995 (NMFS 1995; WDFW 1997).

The Columbia basin annual production ceiling was based on the information on the effects of hatchery fish on listed fish in the migration corridor and ocean. Reviews of the potential effects

of hatchery fish in the migration corridor and ocean are provided by Hard (1994), NMFS (1995) and CBFWA (1996). Currently, the only way to address potential ecological interactions between hatchery and natural fish in the Columbia River basin is through the production ceiling (NMFS 1995), which limits the number of hatchery fish released into the basin. A total of about 72 million anadromous salmonid smolts are released from artificial propagation programs annually. The effects of the 1.1 million steelhead smolts cannot be separated from all other smolt releases, nor can the effects of the entire release be determined at this time. NMFS concludes that the production ceiling protects ESA listed species and finds that based on the best available information of adverse impacts in the migration corridor and ocean that the proposed programs have only minor transitory effects.

4.2.4 Research, Monitoring, and Evaluation

Research, monitoring, and evaluation are a critical component of the three HCP agreements. The adaptive management strategy relies on three hatchery committees (one for each HCP agreement) to provide oversight and recommendations for the artificial propagation programs specified in the HCPs. The enhancement programs will be monitored and evaluated within the hatchery environment and in the natural environment, and will involve both adult and juvenile UCR steelhead components.

4.2.4.1 Hatchery Environment Monitoring

Monitoring activities that occur within the hatchery environment will include biological sampling of both adult and juveniles steelhead. Sampling will be conducted in a manner to extract as much information from as small a sample size as possible to meet the research or investigative needs. No impact to the naturally produced component of the species would occur as a result of the within-hatchery facility research and monitoring activities.

4.2.4.1.1 Juvenile Monitoring

Juvenile monitoring will include routine growth and health sampling on about a monthly basis. This activity will likely result in handling stress, but is not expected to alter the long-term survival of the population. Occasional lethal sampling will occur for health monitoring and to collect tissue samples. This type of sampling will be conducted in a manner to maximize the information collected from each individual killed. For example, juveniles killed for organosomatic index health monitoring, and tissue samples can be used for DNA analysis, thus only one sample group would be collected for both activities. NMFS finds that such sampling provides a net benefit to the ESA-listed artificially propagated population.

4.2.4.1.2 Adult Monitoring

Adult sampling will be coordinated with spawning activities where fish are humanly killed as part of the spawning process. Morphometric samples, sex, mark, tag data, and biological samples such as scales, kidney, spleen and other tissues may be collected. The sampling of adult steelhead after spawning will not increase the level of take or adverse impacts on the species because the steelhead are already dead.

4.2.4.2 Natural Environment Monitoring

The enhancement program will also be monitored outside of the hatchery environment. The monitoring and evaluation program will help identify problems or deviations from the criteria established to measure the expected performance of the supplementation program. The monitoring and evaluation programs will also provide invaluable data on the use of supplementation to conserve and recover ESA-listed salmon species. The proposed action includes the intent to modify the production implementation protocols based on input from these research, monitoring, and evaluation activities.

4.2.4.2.1 Juvenile Monitoring

Monitoring of artificially propagated juvenile steelhead after release will be done using a variety of techniques depending on the investigative objective. Extent and impact of residualizism would be assessed using standard angling and non-lethal sampling techniques and migration rate and tributary productivity would be monitored using juvenile fish traps.

The capture and handling process is likely to cause some stress on ESA-listed fish. Typically, fish recovery rapidly from handling procedures. The primary factors that contribute to stress and mortality from handling are excessive doses of anesthetic, differences in water temperature, dissolved oxygen conditions, the amount of time that fish are held out of water, and physical trauma. Stress on salmonids increases rapidly from handling of the water temperature exceeds 18°C (64.4°F) or dissolved oxygen is below saturation. Also, stress can occur if there are more than a few degrees difference in water temperature between the stream/river and the holding tank. The potential for unexpected injuries or mortalities to ESA-listed fish will be mitigated in a number of ways. Wet hands and keeping fish submerged while measuring will minimize scale and slime removal. Study protocols would include only handling fish during appropriate water temperatures to avoid adding any additional stress and ensuring revival prior to release. The use of sanctuary nets when transferring fish to holding containers will avoid potential injuries. Appropriate anesthetics will be used to calm fish subjected to collection of biological data, captured fish will be allowed to fully recover before being released back into the stream and will be released only in slow water areas. Tagging, such as PIT tagging, of natural origin UCR steelhead juveniles would be used to determine trap efficiency and to assess juvenile seaward migration rate and survival to adult would be determined based on tag detections at dam or recoveries on spawning grounds or in broodstock. The information gained is expected to be very

valuable in increasing our understanding to UCR steelhead populations and life strategies. NMFS finds the measures above to minimize the impacts of the proposed activities adequate to protect the UCR steelhead ESU.

As discussed above in the effects on UCR spring chinook salmon, the WDFW juvenile fish traps are generally operated to achieve a sample efficiency of four to 20 percent of the total run, depending on the river size and the mortality impact would be expected to be less than two percent on target species. Using the largest of the estimates of UCR basin natural production capacity for UCR steelhead of 276,048 (Ford *et al.* 2001) and assuming trap efficiency of 20 percent and mortality of two percent equals an impact of 1,104 smolts. Converting this to adult equivalents (three percent survival smolt-to-adult, Ford *et al.* 2001) results in a maximum loss of up to 33 adult UCR steelhead. Considering that juvenile fish traps will likely not be operated in all tributary basins and will not all achieve an efficiency of 20 percent (for example the lower Wenatchee River trap has previously achieved only about a two percent efficiency), the numeric impact will likely be much less. Based on the highest adult capacity estimate of 8,281 (Ford *et al.* 2001), or the interim abundance target of 5,000 (Lohn 2002), the loss of 33 adult steelhead is not likely to substantially impact the ESU as whole. Again, it is likely mortality from juvenile fish trapping would be much less than this estimate.

4.2.4.2.2 Adult Monitoring

Monitoring of artificially propagated adult steelhead on the spawning grounds will be conducted by air, foot, or float surveys is expected to result in minimal take of UCR steelhead in the form of harassment and collection of tissues from dead steelhead. Potential research or monitoring activities also includes in-water observation of steelhead (i.e., snorkeling). Direct observation is the least disruptive and simplest method of determining presences/absence of the species and can be used to estimate the relative abundance. During some activities redds may be visually inspected, but no redds would be walked on. Potentially, UCR steelhead could experience take in the form of harassment as defined above. However, most activities would not disrupt or injure UCR steelhead. These primarily observational activities will not result in additional mortality of UCR steelhead because carcasses are already dead. The proposed observation, collection of biological data, and tissue samples from carcasses of ESA-listed fish will benefit the species as a whole because of the information gained through these activities will be used in the future to protect, recover, and manage UCR and other steelhead ESUs.

4.3 Cumulative Effects

Cumulative effects are defined in 50 CFR §402.02 as "those effects of future State, tribal, local or private actions, not involving Federal activities, that are reasonably certain to occur in the action area considered in this biological opinion." Future Federal actions, including the ongoing operation of hatcheries, fisheries, and land management activities, are not considered within the category of cumulative effects for ESA purposes because they require separate consultations pursuant to Section 7 of the ESA after which they are considered part of the environmental

baseline. Future State, tribal, local, or private actions within the action area are described for NEPA purposes in the EIS (NMFS 2003) regarding the implementation of the three HCP agreements. NMFS evaluated these actions to determine whether or not they would meet the requirements of its implementing regulations. Those actions which are most notable include Washington State TMDL (total maximum daily load) development and implementation, Washington State legislation to enhance salmon recovery through tributary enhancement programs, and recent human population trends in the action area. However, after considerable review, NMFS has determined that these actions cannot be deemed reasonably likely to occur based on its ESA implementing regulations.

The Endangered Species Consultation Handbook describes this standard as follows:

> "Indicators of actions 'reasonably certain to occur' may include, but are not limited to: approval of the action by State, tribal or local agencies or governments (e.g., permits, grants); indications by State, tribal or local agencies or governments that granting authority for the action is imminent; project sponsors' assurance the action will proceed; obligation of venture capital; or initiation of contracts. The more State, tribal or local administrative discretion remaining to be exercised before a proposed non-Federal action can proceed, the less there is a reasonable certainty the project will be authorized."

There are, of course, numerous non-Federal activities that have occurred in the action area in the past, which have contributed to both the adverse and positive effects of the environmental baseline. This step of the analysis for application of the ESA Section 7(a)(2) standards requires the consideration of what of those past activities are "reasonably certain to occur" in the future within the action area.

First of all, any of these actions that involve Federal approval, funding, or other involvement are not considered "cumulative effects" for this analysis (see ESA definition, above). This Federal involvement will trigger ESA Section 7(a)(2) consultation in the future. Once the consultation on those actions is completed the effects may be considered part of the environmental baseline, consistent with the ESA regulatory definition of "effects of the action" (50 CFR §402.02). Thus, for example, state efforts to improve water quality in compliance with the Federal Clean Water Act would not be considered because of the involvement of the EPA, until separate ESA consultations are completed. Others examples include irrigation water withdrawals involving the

USFS (right-of-way permits for irrigation canals) or agricultural practices that receive Federal funding through the U.S. Department of Agriculture.

Next, actions that do not involve Federal activities must meet the "reasonably certain to occur" test for NMFS to consider their effects in this Opinion. Recognizing that this is a narrower standard than used for NEPA purposes, not all of the actions identified in the EA may be considered as "cumulative effects" for this ESA Section 7(a)(2) consultation. In reviewing the

actions identified in cumulative effects analysis of the EA, after eliminating from consideration those with Federal involvement, NMFS finds that currently few, if any, of the future adverse or beneficial State, tribal or private actions qualify for consideration in this analysis as "cumulative effects."

Therefore, when evaluating the status of the listed species, including their likelihood of survival and recovery, NMFS concludes that most of the factors for the decline of these species are not eligible for consideration in determining whether the authorization of incidental take under this HCP is likely to jeopardize their continued existence. Thus the future abundance and productivity of the listed UCR steelhead and UCR spring-run chinook salmon, against which the effects of this action are considered, are likely to be improved, although to an unknown or possibly minor extent, over those reflected by the historical trends under the environmental baseline.

4.4 Integration and Synthesis

The proposed UCR steelhead artificial propagation programs pose minimal risk to the UCR spring chinook salmon ESU. Operation of the hatchery facilities in which UCR steelhead are reared is not likely to substantially affect the water quality characteristics or water quantity, because of minimization measures in place and NPDES permit requirements and water right restrictions. Adult UCR spring chinook salmon and UCR steelhead return and spawn at different times of the year and therefore UCR spring chinook salmon adults are not expected to be affected by returning adult artificially propagated UCR steelhead. Juvenile UCR spring chinook salmon could be minimally impacted by the release of artificially propagated UCR steelhead smolts. The proposed actions include measures to minimize impacts which include releasing only migration ready steelhead smolts. Capture, handling, and release of UCR spring chinook juveniles could occur during some monitoring and evaluation activities. The mortality impacts to the ESU would be small in comparison to the total UCR spring chinook smolt production capacity of the UCR basin. Furthermore, juvenile fish traps used to monitor UCR steelhead are likely to be used to monitor UCR spring chinook salmon as authorized in permit 1203.

The proposed actions of the enhancement programs involve the direct taking of up to 581 UCR steelhead, of which only up to 216 would be natural origin UCR steelhead. The collection of five percent of the average UCR steelhead run for the production of up to 889,000 smolts released in the UCR basin and 180,000 smolts released from Ringold Springs Rearing Facility is intended to facilitate recovery of the ESU by enhancing natural reproduction of UCR steelhead in the Wenatchee, Methow and Okanogan basins.

The permit applicants identified specific artificial propagation program impact minimization measures which NMFS further defines through section 10 permit terms and conditions, which together provide substantial protection to the UCR steelhead ESU. The monitoring and evaluation, and research projects will provide more information on the reproductive success of artificially propagated steelhead and program implementation changes to ensure the programs

achieve the enhancement objective. Juvenile monitoring could result in a maximum, but likely substantially less than, a lethal take of two percent of the UCR steelhead smolts. This translates into a numeric reduction of about 33 adult steelhead for the entire ESU. Annual reporting requirements for each permit holder provides NMFS with a mechanism to ensure that the assumptions of the analysis and the impact limits are not violated.

NMFS must weigh the potential benefits with the potential adverse effects when deciding whether the contemplated actions will appreciably reduce the likelihood of the UCR spring chinook ans steelhead survival and recovery - the critical determination in issuing any biological opinion.

5. CONCLUSION

NMFS has determined, after reviewing the current status of UCR steelhead, the environmental baseline for the action area, the effects of the proposed section 10(a)(1)(A) actions, and the cumulative effects, that the issuance of the multi-year section 10(a)(1)(A) permits to the WDFW, the Chelan PUD, and the Douglas PUD (permit 1395), the USFWS (permit 1396), and the Colville Tribes (permit 1412) for an annual take of endangered UCR steelhead for scientific research and enhancement of UCR steelhead is not likely to jeopardize the continued existence of UCR steelhead and UCR spring chinook salmon. Furthermore, the supplementation programs covered by the permits are expected to provide a survival benefit to UCR steelhead by increasing the natural production of Wenatchee, Methow and Okanogan basins.

6. INCIDENTAL TAKE STATEMENT

Section 9 and rules promulgated under subsection 4(d) of the ESA prohibit the take (harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, collect, or attempt to engage in any such conduct) of listed species without a specific permit or exemption. Harm is defined as "an act that may include significant habitat modification or degradation where it actually kills or injures fish by impairing breeding, spawning, rearing, migration, feeding or sheltering." Harass is defined as " actions that create the likelihood of injuring listed species to such an extent as to significantly alter normal behavior patterns which include, but are not limited to, breeding, feeding, or sheltering. Incidental take is take of listed species that results from, but is not the purpose of, the Federal agency or the applicant carrying out an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to, and not intended as part of, the agency action is not considered prohibited taking provided that such taking is in compliance with the terms and conditions of this ITS. [50 CFR §402.14(I)(3)]

An ITS specifies the impact of any incidental taking of endangered or threatened species. It also provides reasonable and prudent measures that are necessary to minimize the effect of incidental

take and sets forth terms and conditions with which the action agency must comply in order to implement the reasonable and prudent measures.

6.1 Amount or Extent of Take Anticipated

The measures described in this section are non-discretionary and must be included in the ITS issued by NMFS. NMFS' proposed action of issuing a section 10(a)(1)(A) permit is designed to minimize incidental take of listed species. The proposed UCR steelhead artificial propagation programs are reasonably certain to result in incidental take of UCR spring chinook salmon because juvenile UCR spring chinook salmon are known to occur in the action area.

Adult UCR spring chinook salmon are not expected to be impacted during any of the activities associated with the proposed programs because they are generally not in the action area at the same time as adult steelhead, nor are they present during the spring months when juvenile steelhead would be released from hatchery facilities.

No incidental takes of ESA-listed species are expected to occur as a result of within-hatchery monitoring and evaluation associated with the proposed programs. Incidental takes of listed species associated with monitoring and evaluation outside of the hatchery environment may occur depending on the monitoring activity.

Visual Observation techniques employed in the natural environment such as redd counts and snorkeling do not involve collection or physical contact with UCR spring chinook salmon or other species. These activities may result in temporary displacement of juvenile UCR spring chinook salmon from local habitats for brief periods of time. The impacts of this type of activities are currently unquantifiable but are expected to be small.

Monitoring of juvenile steelhead released from hatchery facilities or that are progeny of hatchery origin steelhead that spawned in the natural environment using techniques such as juvenile fish traps may result in the capture, handling, and release of juvenile UCR spring chinook salmon. It is expected that such monitoring activities would be conducted to minimize potential adverse impacts on UCR spring chinook salmon and likely included spring chinook salmon monitoring as a study objective. If a monitoring activity such as juvenile fish trapping does not included collection of UCR spring chinook salmon as an objective authorized under a separate ESA consultation the mortality impact on UCR spring chinook salmon juveniles should not exceed one percent of the UCR spring chinook salmon encountered in the trap.

6.2 Effects of the Take

In the accompanying biological opinion, NMFS determined that the level of anticipated take described above is not likely to result in jeopardy to the listed species.

6.3 Reasonable and Prudent Measures

Reasonable and Prudent Measures (RPMs) are non-discretionary measures to minimize take, that may or may not already be part of the description of the proposed action. They must be implemented as binding conditions for the exemption in section 7(o)(2) to apply. NMFS has the continuing duty to regulate the activities covered by this ITS. If NMFS fails to require the applicants to adhere to the terms and conditions of this ITS through enforceable terms that are added to the permits or grant documents, or fails to retain the oversight to ensure compliance with these terms and conditions, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the WDFW, the Chelan PUD, and the Douglas PUD, the USFWS, and the Colville Tribes must report the progress of their actions and the respective impacts on the species to NMFS as specified in this ITS. NMFS believes that activities carried out in a manner consistent with these reasonable and prudent measures, except those otherwise identified, will not necessitate further site-specific consultation. Activities which do not comply with al relevant reasonable and prudent measures will require further consultation.

In order to issue the multi-year section 10(a)(1)(A) permits for the proposed actions, NMFS believes that the following reasonable and prudent measures are necessary and appropriate to minimize the incidental take of ESA-listed species associated with the UCR steelhead artificial propagation programs and the monitoring and evaluation efforts:

1. The applicants should minimize the incidental take of ESA-listed species associated with the artificial propagation programs by using observational techniques whenever possible to meet monitoring and evaluation objectives.

2. The applicants should have as a long-term management target no more than 20 percent of the spawners being of hatchery origin in the Wenatchee and Methow basins and no more than 50 percent in the Okanogan basin once recovery goals are achieved.

6.4 Terms and Conditions

In order to be exempt from the prohibitions of section 9 of the ESA, the program operating entities must comply with the following terms and conditions, which implement the reasonable and prudent measures described above. These terms and conditions are not discretionary and are valid for the duration of the respective permits:

1. The WDFW, the USFWS and the Colville Tribes shall monitor the incidental take of ESA-listed species, including endangered, naturally produced, UCR spring chinook salmon and UCR steelhead, as a result of juvenile fish releases from the artificial propagation program. As part of the monitoring effort, the program operating entities shall attempt to determine the extent to which artificially propagated juvenile steelhead released from the program interact positively or negatively with the UCR spring chinook salmon's natural production in the region.

2. Annual reports shall be provided to the Salmon Recovery Division, NMFS, documenting the incidental take of ESA-listed species associated with the endangered UCR steelhead artificial propagation programs by January 31st of each year the permit is in effect.

7. REINITIATION OF CONSULTATION

This concludes formal consultation of the actions outlined in the applications for section 10(a)(1)(A) permits. As provided in 50 CFR §402.16, reinitiation of formal consultation is required if: (1) the amount or extent of annual take, either intentional take or incidental take, is exceeded or is expected to be exceeded; (2) new information reveals effects of the agency action that may affect listed species in a way not previously considered; (3) the action is modified in a way that causes an effect to listed species that was not previously considered; or (4) a new species is listed or critical habitat is designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, the operation that resulted in exceeding take must cease, and consultation must be reinitiated.

8. MAGNUSON-STEVENS ACT ESSENTIAL FISH HABITAT CONSULTATION

8.1 Background

The Magnuson-Stevens Fishery Conservation and Management Act (MSA), as amended by the Sustainable Fisheries Act of 1996 (Public Law 104-267), established procedures designed to identify, conserve, and enhance Essential Fish Habitat (EFH) for those species regulated under a Federal fisheries management plan. Pursuant to the MSA:

- Federal agencies must consult with NMFS on all actions, or proposed actions, authorized, funded, or undertaken by the agency, that may adversely affect EFH (§305(b)(2));
- NMFS must provide conservation recommendations for any Federal or State action that would adversely affect EFH (§305(b)(4)(A));
- Federal agencies must provide a detailed response in writing to NMFS within 30 days after receiving EFH conservation recommendations. The response must include a description of measures proposed by the agency for avoiding, mitigating, or offsetting the impact of the activity on EFH. In the case of a response that is inconsistent with NMFS EFH conservation recommendations, the Federal agency must explain its reasons for not following the recommendations (§305(b)(4)(B)).

Essential Fish Habitat means those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity (MSA §3). For the purpose of interpreting this definition of EFH:

Waters include aquatic areas and their associated physical, chemical, and biological properties that are used by fish and may include aquatic areas historically used by fish where appropriate; substrate includes sediment, hard bottom, structures underlying the waters, and associated biological communities; necessary means the habitat required to support a sustainable fishery and the managed species' contribution to a healthy ecosystem; and "spawning, breeding, feeding, or growth to maturity" covers a species' full life cycle (50 CFR §600.10). Adverse effect means any impact which reduces quality and/or quantity of EFH, and may include direct (e.g., contamination or physical disruption), indirect (e.g., loss of prey or reduction in species fecundity), site-specific or habitat-wide impacts, including individual, cumulative, or synergistic consequences of actions (50 CFR §600.810).

Consultation with NMFS is required regarding any Federal agency action that may adversely affect EFH, including actions that occur outside EFH, such as certain upstream and upslope activities.

The objectives of this EFH consultation are to determine whether the proposed action would adversely affect designated EFH and to recommend conservation measures to avoid, minimize, or otherwise offset potential adverse effects to EFH.

8.2 Identification of Essential Fish Habitat

Pursuant to the MSA, the Pacific Fisheries Management Council (PFMC) has designated EFH for three species of federally-managed Pacific salmon: chinook; and coho (*O. kisutch*); and Puget Sound pink salmon (*O. gorbuscha*)(PFMC 1999). Freshwater EFH for Pacific salmon includes all those streams, lakes, ponds, wetlands, and other water bodies currently, or historically accessible to salmon in Washington, Oregon, Idaho, and California, except areas upstream of certain impassable man-made barriers (as identified by the PFMC 1999), and longstanding, naturally-impassable barriers (i.e., natural waterfalls in existence for several hundred years). Detailed descriptions and identifications of EFH for salmon are found in Appendix A to Amendment 14 to the Pacific Coast Salmon Plan (PFMC 1999). Assessment of potential adverse effects to these species' EFH from the proposed action is based, in part, on this information.

8.3 Proposed Action and Action Area

For this EFH consultation, the proposed actions and action area are as described in this Opinion above. The actions are the issuance of scientific research/enhancement permits pursuant to section 10(a)(1)(A) of the ESA for the implementation of artificial propagation programs rearing ESA-listed UCR steelhead. The proposed action area is the UCR basin, including all river reaches accessible to salmon in the Wenatchee, Methow, and Okanogan River basins in Washington and is part of the EFH for chinook salmon and coho salmon. The proposed actions may also affect EFH in the lower Columbia River and near ocean areas; however, NMFS does not believe it is possible to meaningfully measure, detect or evaluate the effects of those actions in these areas, and, consequently, NMFS will not include EFH subject to these effects in the

action area. Assessment of the impacts on these species' EFH from the above proposed action is based on this information.

8.4 Effects of the Proposed Action

As described in detail above of this Opinion, the proposed action may result in adverse effects to EFH. These adverse effects are:

- Water quality impacts from water withdrawal and hatchery effluent.
- Adult passage impediments due operation of weirs used for broodstock collection.
- Predation of natural juvenile salmonids by artificially propagated fish.
- Competition for resources between artificially propagated and natural salmonids.
- Exchange of disease pathogens between artificially propagated and natural salmonids.

8.5 Conclusion

NMFS concludes that the proposed action would adversely affect designated EFH for chinook salmon.

8.6 EFH Conservation Recommendation

Pursuant to Section 305(b)(4)(A) of the MSA, NMFS is required to provide EFH conservation recommendations to Federal agencies regarding actions which may adversely affect EFH. NMFS understands that the conservation measures described in the Permit Applications, this Opinion are applicable to designated salmon EFH and address the adverse effects. Therefore, NMFS recommends that those same Conservation Measures and Terms and Conditions be adopted as the EFH Conservation Recommendations for this consultation.

8.7 Statutory Response Requirement

Pursuant to the MSA (§305(b)(4)(B)) and 50 CFR §600.920(j), Federal agencies are required to provide a detailed written response to NMFS' EFH conservation recommendations within 30 days of receipt of these recommendations. The response must include a description of measures proposed to avoid, mitigate, or offset the adverse impacts of the activity on EFH. In the case of a response that is inconsistent with the EFH conservation recommendations, the response must explain the reasons for not following the recommendations, including the scientific justification for any disagreements over the anticipated effects of the proposed action and the measures needed to avoid, minimize, mitigate, or offset such effects.

8.8 Consultation Renewal

The NMFS must reinitiate EFH consultation if the proposed actions are substantially revised in a way that may adversely affect EFH, or if new information becomes available that affects the basis for NMFS' EFH conservation recommendations (50 CFR §600.920(k)).

1 PURPOSE, SCOPE, AND AREA OF THE PROPOSED ACTION

1.1 Introduction

The U.S. Department of Commerce, NOAA' National Marine Fisheries Service (NMFS), is evaluating the decision to authorize, in accordance with the Endangered Species Act (ESA), section 10(a)(1)(A) direct take research/enhancement permits, numbers 1395, 1396, and 1412. These three permits would authorize take of listed salmon and steelhead during operation of steelhead artificial propagation programs and associated research activities in the upper Columbia River by the Washington Department of Fish and Wildlife (WDFW), the Public Utility District No. 1 of Chelan County (Chelan PUD), and the Public Utility District No. 1 of Douglas County (Douglas PUD), the U.S. Fish and Wildlife Service (USFWS), and the Confederated Tribes of the Colville Reservation (Colville Tribes) (permit applicants). Of these applicants, the WDFW, the USFWS, the Colville Tribes, in additional to NMFS and the Tribes and Bands of the Yakima Nation, are considered co-managers of the fishery resources in the upper Columbia River Basin.

The Upper Columbia River steelhead (*Oncorhynchus mykiss*) Evolutionarily Significant Unit (ESU) was listed as endangered on August 18, 1997 (62 FR 43937) (Figure 1). Potential environmental effects come as a result of adult monitoring and management of artificially propagated returning adult Upper Columbia River steelhead, the artificial propagation activities, and associated research requested by the permit applicants. These activities include random sampling of returning adult Upper Columbia River steelhead, collecting adult ESA-listed Upper Columbia River steelhead, spawning adults in a hatchery environment, rearing juveniles to the smolt stage, releasing the smolts in the respective basin of origin, conducting propagation program specific scientific research and monitoring activities, and managing the returning adult hatchery steelhead. Initial program implementation is based on continued use, and modification as necessary, of existing hatchery facilities built in the middle and upper Columbia River Region for steelhead production. Progeny derived from the Upper Columbia River steelhead ESU, even when artificially propagated, remain listed under the ESA (April 5, 1993, 58 FR 17573). Permit issuance actions are expected to directly affect only the Upper Columbia River steelhead ESU. However, endangered Upper Columbia River spring chinook salmon (*O. tshawytscha*) and threatened bull trout (*Salvelinus confluentus*) may be indirectly taken during the proposed activities.

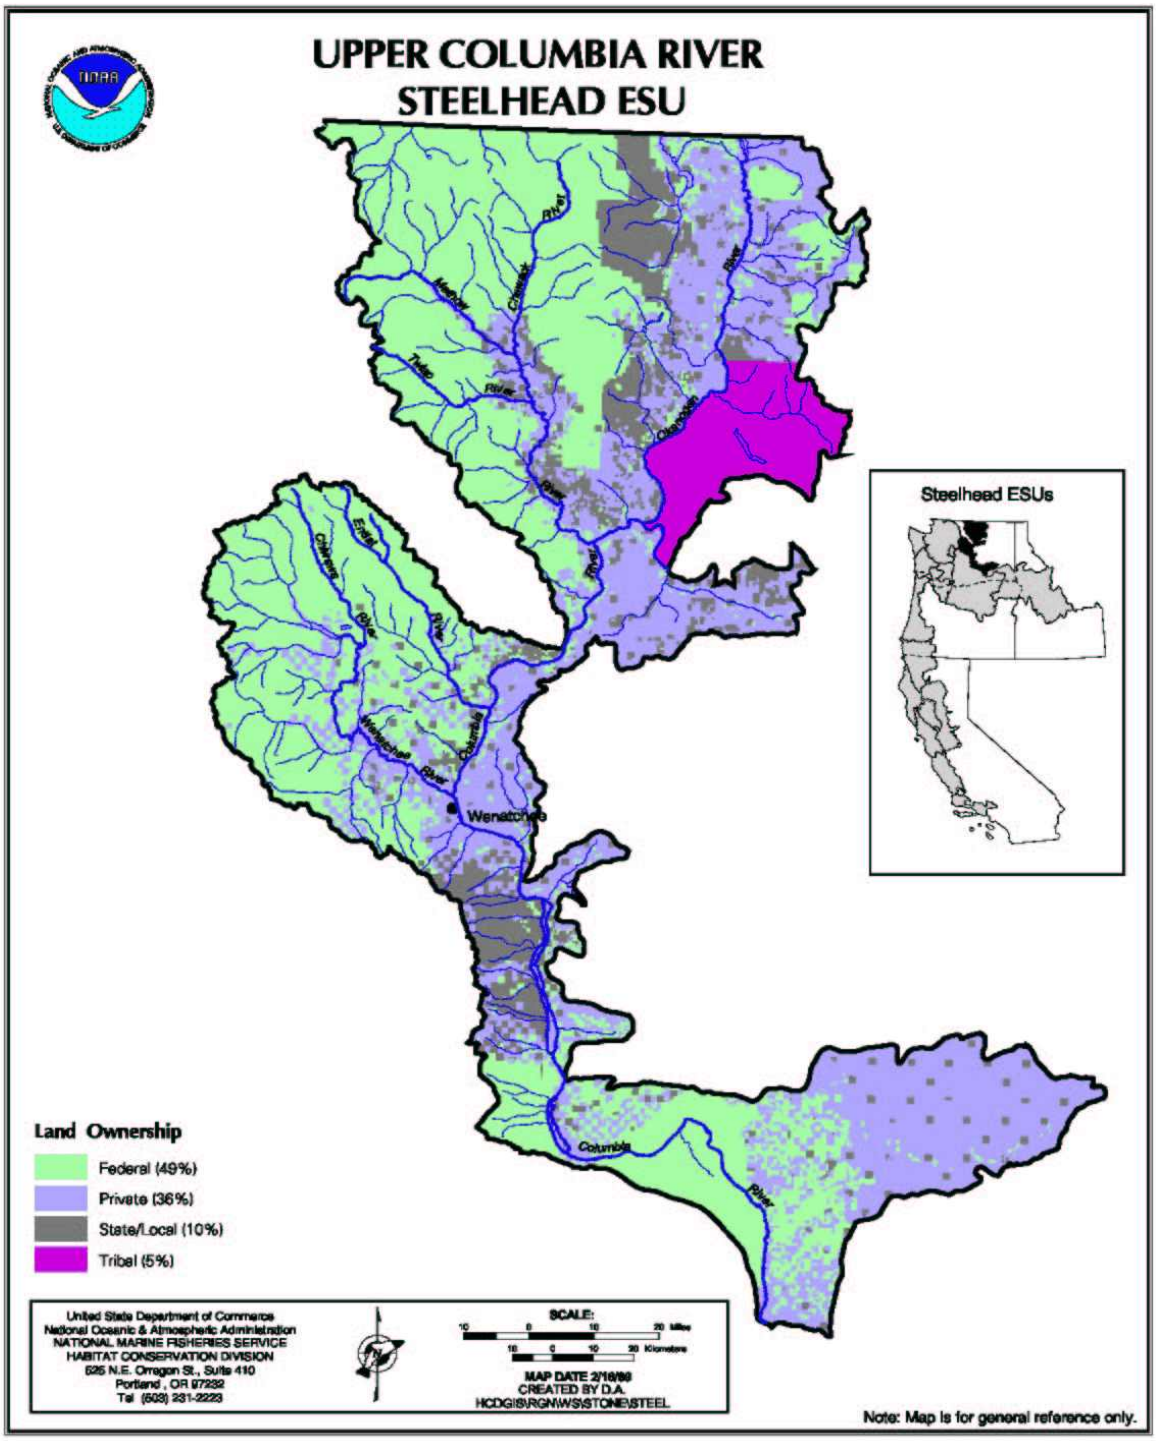

Figure 1. Upper Columbia River Steelhead ESU.

1.2 Background

On June 12, 2002, NMFS received an application for an ESA section 10 permit from the WDFW (WDFW 2002) requesting a multi-year authorization for an annual take of Upper Columbia River steelhead and Upper Columbia River spring chinook salmon associated with proposed steelhead artificial propagation programs intended to enhance the natural production of ESA-listed Upper Columbia River steelhead.

In April 2002, negotiations on the *Anadromous Fish Agreement and Habitat Conservation Plan for Rocky Reach Hydroelectric Project* (Federal Energy Regulatory Commission (FERC) License Number 2145), the *Anadromous Fish Agreement and Habitat Conservation Plan for Rock Island Hydroelectric Project* (FERC License Number 943), and the *Anadromous Fish Agreement and Habitat Conservation Plan for Wells Hydroelectric Project* (FERC License Number 2149), hereafter referred to as the three HCPs, were completed relating to the re-licensing of Wells Dam with Douglas PUD (DPUD 2002), and Rocky Reach Dam, and Rock Island Dam with Chelan PUD (CPUD 2002a; 2002b). These long-term agreements between NMFS, the PUDs, the WDFW, the USFWS, the Colville Tribes, and other stake holders that elect to sign the agreements, provide Chelan and Douglas PUDs with hydropower project operational certainty into the future in exchange for mitigation in the form of a tributary fund for habitat improvement projects and artificial propagation programs to replace unavoidable losses to natural fish production. The artificial propagation component of each HCP specifies the number and species to be reared. Each of the three HCP agreements specifically require artificial propagation of steelhead as a mitigation action. The HCP agreements stipulate that the Chelan and Douglas PUDs would be issued the ESA permits necessary to implement the artificial propagation programs.

In addition, on June 11, 2002, NMFS received a similar application for an ESA section 10 permit from the USFWS, requesting a multi-year authorization for an annual take of Upper Columbia River steelhead and Upper Columbia River spring chinook salmon associated with a steelhead artificial propagation program in the Methow River Basin (USFWS 2002). This program has long-term stable funding from the Bureau of Reclamation (BOR) with production goals set by the Columbia River Fisheries Management Plan under the *U.S. v. Oregon* decision of 1969. The program would be operated in a manner consistent with enhancing the natural steelhead population.

Lastly, on October 23, 2002, NMFS received an application for a section 10 permit from the Colville Tribes, requesting a multi-year authorization for an annual take of Upper Columbia River steelhead and Upper Columbia River spring chinook salmon associated with a steelhead artificial propagation program in the Okanogan River Basin (CCT 2002). Funding for this program has been allocated through the Pacific Salmon Coastal Recovery Fund administered by NMFS, and is consistent with BOR steelhead recovery efforts ongoing in the Okanogan Basin. The program would be operated in a manner consistent with enhancing the natural steelhead population.

1.3 Purpose of and Need for the Proposed Action

NMFS proposes to issue three ESA section 10(a)(1)(A) permits for annual takes of Upper Columbia River spring chinook salmon and Upper Columbia River steelhead: permit 1395 would be issued jointly to the WDFW, Chelan PUD, and Douglas PUD to carry out activities associated with the steelhead artificial propagation programs funded by Chelan and Douglas PUDs and operated by WDFW, permit 1396 would be issued to the USFWS to carry out activities associated with a steelhead artificial propagation program in the Methow River, and permit 1412 would be issued to the Colville Tribes to carry out activities associated with a steelhead artificial propagation program in Omak Creek, a tributary of the Okanogan River.
The purpose of and need for the issuance of these section 10 permits is to ensure the continuation of the programs and their implementation as well as compliance with the ESA. Actions that may affect listed species are reviewed by NMFS through section 7 or section 10 of the ESA. Under section 10 of the ESA, non-federal entities may apply for permits from NMFS to take ESA-listed species under the jurisdiction of NMFS if such taking is for scientific purposes or to enhance the propagation or survival of the affected species.

Issuance of the three permits is needed to fulfill NMFS' obligations outlined in the three HCPs, which include the requirement to use artificial propagation techniques to replace unavoidable steelhead losses associated with operation of Wells Dam, Rocky Reach Dam, and Rock Island Dam, and meet Federal court mandates. Permit conditions would help ensure that the proposed programs are operated to protect and enhance the endangered Upper Columbia River steelhead ESU and remain compliant with the ESA.

1.4 Scope of Action

The action considered here includes only issuance of the three section 10 permits to implement the artificial propagation research/enhancement programs as requested and their affect on the environment within the action area. Other activities in the Columbia River Basin, and other harvest activities outside the Columbia River Basin, might have impacts on the abundance and survival of the ESA-listed species. NMFS does not expect that the proposed action would measurably impact listed salmonid populations outside of the action area because artificially propagated steelhead associated with the proposed programs would be in the migration corridor for less than a month, and would entail a small fraction of the total number of artificially propagated anadromous fish released in the Columbia River Basin. In addition, several hatchery reform measures have been implemented to limit interactions between natural and hatchery salmonids while in the migration corridor (NMFS 1999).

NMFS has proposed and evaluated the action of issuing incidental take statements for the three HCPs as its preferred alternative in the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002).

1.5 Action Area

The action area of this EA is within the upper Columbia River Basin and includes areas primarily in Chelan, Douglas, and Okanogan Counties. More specifically, the action area includes the Columbia River at and above Priest Rapids Dam, the Wenatchee River, Methow River, and Okanogan River Basins and artificial propagation facilities along the mainstem Columbia River. Figure 2 identifies the primary hatchery facilities, trap locations, and hydropower projects pertinent to this EA.

The action area in the Wenatchee River Basin includes the Chiwawa River, Nason Creek, Dryden and Tumwater Dams, and all tributaries accessible to anadromous steelhead. The watershed encompasses approximately 1,327 square miles, with 230 miles of major streams and rivers and enters the Columbia River at river mile (RM) 468.

The action area in the Methow River Basin includes the Methow River, Twisp River, Chewuch River, the Methow Fish Hatchery, the Winthrop National Fish Hatchery, and various smaller tributaries that are accessible to steelhead. The Methow River watershed encompasses about 1,800 square miles and enters the Columbia River at RM 524. The Methow Fish Hatchery is located at approximately RM 44 on the Methow River, and the Winthrop National Fish Hatchery is located at about RM 43.5 on the Methow River.

The action area in the Okanogan River Basin includes the Okanogan River, Similkameen River, Omak Creek, and Salmon Creek, and other small tributaries that are accessible to steelhead. The Okanogan River watershed encompasses about 8,900 square miles and is located in north central Washington with its source on the eastern slopes of the Cascade Mountains in Canada, and flows southward to enter the Columbia River at RM 535.

The Wells, Rocky Reach, and Rock Island hydropower projects are part of an 11-dam system on the mainstem Columbia River within the continental United States. Most of the projects on the mainstem Columbia River are federally operated, although local PUDs operate five of the projects in the Mid-Columbia River segment. In addition to the three projects operated by the Chelan and Douglas County PUDs, the PUD No. 2 of Grant County operates the Priest Rapids and Wanapum Dams (Priest Rapids Project).

The Douglas County PUD operates the Wells Project located at RM 516 on the Columbia River, north of the City of Wenatchee. Wells began commercial operations on August 22, 1967, and is operated under a license issued by FERC, which expires in the year 2012.

Chelan County PUD operates the Rocky Reach and Rock Island hydroelectric projects. Rocky Reach Dam is located about 8 miles upstream from the City of Wenatchee, at RM 475. The Federal Power Commission issued the original operating license for Rocky Reach on July 11, 1957. The license expires in 2006. Rock Island, which was the first hydroelectric project to span the Columbia River, is located about 13 miles downstream from the City of Wenatchee at Rock Island began operating in 1933, and its operating license expires in the year 2028.

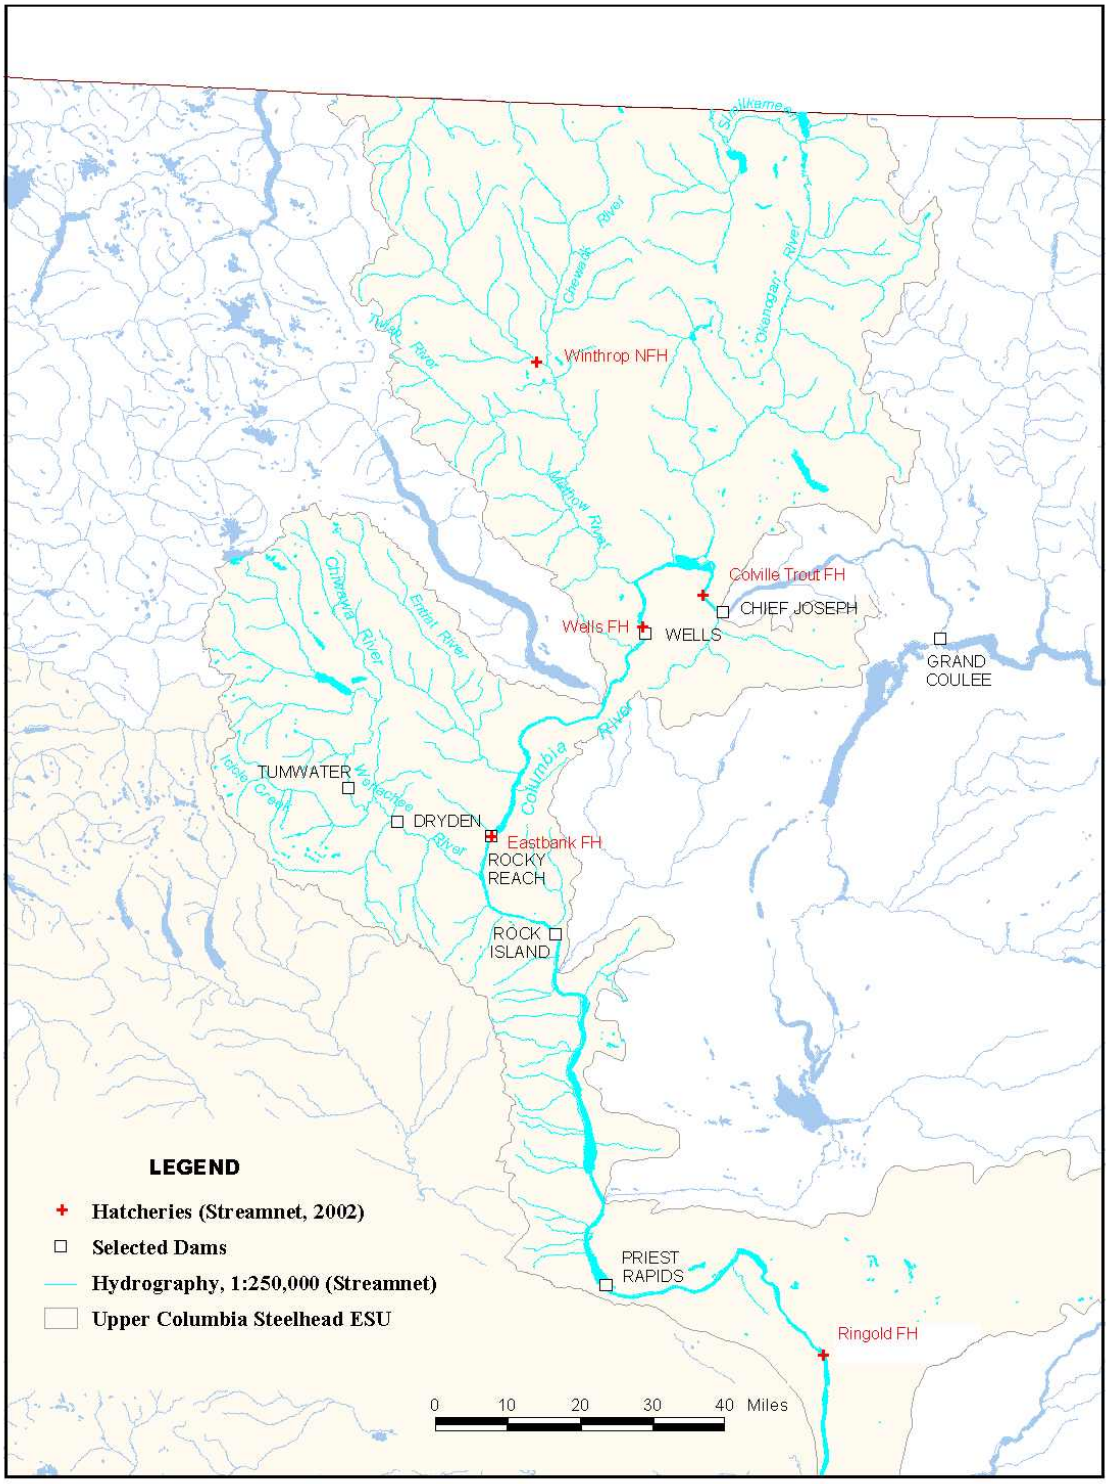

Figure 2. Location of dams and hatchery facilities that rear ESA-listed steelhead in the upper Columbia River Basin.

The project boundaries include the forebay (from the dam to approximately 500 feet upstream), tailrace (from the dam to approximately 1,000 feet downstream), and reservoir associated with each dam. The Wells reservoir extends approximately 30 miles upstream of the dam to the Chief Joseph Dam tailrace, the Rocky Reach reservoir extends approximately 41 miles upstream of the dam to the Wells tailrace, and the Rock Island reservoir extends approximately 20 miles upstream of the dam to the Rocky Reach tailrace. Considering all components of the three projects, the entire project area extends from the tailrace of the Rock Island Dam upstream to the tailrace of Chief Joseph Dam (approximately 92 miles).

Interactions between fish released from the proposed artificial propagation programs and other anadromous species in the Columbia River downstream of the proposed action area were considered by NMFS. Determining the nature of these transient interactions that occur during migration are difficult due to the biological attributes of salmon and steelhead, the dimensions and variability in the Columbia River system, and the cycles in the ocean environment. Based on the large scale of the Columbia River, the level of proposed artificial propagation relative to the artificial propagation programs in the Columbia River Basin, and the limited period of interaction during active migration, NMFS has determined that impacts on anadromous fish below the action area are not likely to occur at a magnitude requiring analysis at the level of this assessment. For example, at the mouth of the Columbia River, artificially propagated steelhead associated with the proposed programs would comprise only about 1.5 percent of artificially propagated anadromous fish released annually (less than 1.1 million steelhead of 71 million total salmonid releases in 2001) and would be expected to be in the estuary for only a few weeks. In addition, several hatchery reform measures have been implemented to limit interactions between natural and hatchery salmonids while in the migration corridor (NMFS 1999).

1.6 Relationships to Other Plans and Policies

This EA was prepared pursuant to regulations implementing the NEPA (42 USC 4321), and in compliance with federal regulations for preparing an EA (40 CFR 1502). Please refer to the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002) for an in depth discussion of the other plans and policies that could be affected by the Proposed Actions analyzed in this EA, which would be identical.

2 ALTERNATIVES INCLUDING THE PROPOSED ACTION

The proposed action and two alternatives considered in this EA are: (1) to not issue the permits (no action), (2) to issue the permits without conditions, and (3) to issue the permits with conditions (proposed action). The following describes the alternatives.

2.1 Alternative 1 - Do Not Issue the Permits (No Action)

Under a No Action alternative, NMFS would not issue the ESA section 10(a)(1)(A) permits authorizing direct take of ESA-listed species associated with the requested activities. This alternative would effectively prohibit the sampling of adult steelhead, collection of ESA-listed fish for broodstock, rearing of juvenile steelhead to the smolt stage, release of yearling age smolts, purposeful management of returning propagated adult steelhead for the enhancement of naturally spawning population, and further research on the utility of artificial propagation to enhance and assist in the recovery of the ESA-listed population in the action areas because the activities would likely be in violation of the ESA. Take limit regulations under ESA section 4(d) are not available to the permit applicants because the Upper Columbia River steelhead are listed as Endangered rather than Threatened. The programs could be terminated or altered to rear non-listed species, although neither of these options would satisfy the stated purpose and need as described above because the artificial propagation of steelhead is a specific requirement of the three HCPs and is likely necessary for recovery of the ESA-listed species. For the purpose of this analysis NMFS assumes that the steelhead programs would be discontinued in the absence of these section 10 permits.

2.2 Alternative 2 - Issue Permits Without Conditions

Alternative 2 would encompass the issuance of permits under section 10(a)(1)(A) of the ESA unconditionally based strictly on the applications and the three HCPs submitted. The permits would authorize the take of listed species, but no special conditions would be imposed. The applications and HCPs describe activities for co-manager program oversight, large scale monitoring, program operational detail, and purposeful management of adult artificially propagated steelhead returning to the upper Columbia River Basin. The application reflects the adoption of protocols for artificial propagation of ESA-listed species that are risk-averse and include the most current science on management of hatchery facilities and genetic impacts of artificial propagation. With the exception that special conditions would not be imposed by NMFS, the description of this alternative mirrors the description of the proposed action (Section 2.3, Alternative 3, below) and does meet the ESA section 10 criteria for a permit application.

2.3 Alternative 3 - Issue Permits With Conditions (Proposed Action)

The action proposed is to issue three permits under section 10(a)(1)(A) of the ESA based on the applications and the three HCPs, including attachments, submitted by the WDFW, the Chelan and Douglas PUDs, the USFWS, and the Colville Tribes as modified by the conditions that NMFS may require as being necessary and appropriate. The NMFS conditions would ensure that the annual take of ESA-listed anadromous fish would be for the propagation and enhancement of

the ESA-listed steelhead population, the associated scientific research and monitoring activities, and the purposeful management of adult artificially propagated steelhead returns in excess to natural production needs. The conditions imposed by NMFS would also help to ensure that the annual take would not appreciably reduce the likelihood of the survival and recovery of the species in the wild. Pursuant to section 10, the permit would contain terms and conditions necessary to the propagation or survival of listed steelhead, including reporting requirements for determining whether such terms and conditions are being complied with.

2.3.1 Permit 1395 Proposed Activities

The WDFW permit application (WDFW 2002) and the three HCPs (DPUD 2002; CPUD 2002a; 2002b) include activities associated with the management of ESA-listed steelhead artificial propagation programs. These activities are proposed for a 10-year period commencing in 2003. Through these programs, adult steelhead broodstock within the Upper Columbia River ESU would be intentionally taken for the purpose of determining annual run composition, to assist managers in decision making, and for broodstock in order to artificially propagate the progeny to the yearling smolt stage and release them into the Wenatchee, Methow, and Okanogan River Basins for the purpose of enhancing the natural population. The resultant returning adult steelhead would be purposely managed to ensure adequate spawning escapements into each basin with an emphasis on the perpetuation of natural-origin steelhead. The co-managers would develop plans each year for utilizing the returning steelhead, based on desired proportions of artificially propagated fish on natural spawning grounds, using any of a variety of mechanisms for managing the proportions, such as removal at dams or in selective recreational fisheries. Proposals for harvest activities in any year in which they occur would be subject to review and approval by NMFS. Proposed activities that would lead to the take of the ESA-listed species are described below and summarized in Table 1.

2.3.1.1 Adult Return Monitoring

The WDFW proposes to conduct random sampling of the annual adult steelhead run returning to the Upper Columbia River Basin at Priest Rapids Dam to enable informed decisions to be made concerning the management of ESA-listed Upper Columbia River steelhead. The sampling activities that would affect ESA-listed species are provided in Table 1.

2.3.1.2 Adult Return Management

The WDFW proposes to purposely manage artificially propagated adult steelhead returning to the upper Columbia River Basin. Based on the monitoring at Priest Rapids Dam recommendations concerning broodstock collection strategies and the potential for other actions to utilize any excess hatchery steelhead would be made each year. Recommendations concerning management of hatchery steelhead proportions on spawning grounds and a means by which to remove excess hatchery steelhead would be made individually for the Wenatchee, Methow, and Okanogan Basins. Activities that would affect ESA-listed species are provided in Table 1.

2.3.1.3 Artificial Propagation

Two hatchery facility complexes are operated by the WDFW within the middle and upper Columbia River Basin for the propagation of steelhead: Wells Fish Hatchery Complex and Eastbank Fish Hatchery Complex. The proposed artificial propagation programs are funded by Chelan and Douglas PUDs as mitigation for hydropower project operation impacts to the naturally spawning steelhead populations present in the Wenatchee, Methow, and Okanogan River Basins. The Wells Fish Hatchery Complex uses returning steelhead adults collected at Wells Dam on the Columbia River to supplement steelhead populations in the Methow and Okanogan River Basins. The Eastbank Fish Hatchery Complex uses steelhead broodstock collected at Dryden and Tumwater Dams on the Wenatchee River to supplement steelhead populations in the Wenatchee River Basin. Activities that would affect ESA-listed Upper Columbia River steelhead are provided in Table 1.

2.3.1.4 Research, Monitoring, and Evaluation

Research, monitoring, and evaluation are critical components of the proposed programs. The three HCP agreements specifically require the formation of Hatchery Committees consisting of representatives from each signatory entity to each HCP. These HCP Hatchery Committees are charged with oversight of the artificial propagation programs to ensure that the programs are effective in meeting co-manager defined goals and objectives. The Upper Columbia River steelhead programs are intended to support naturally-spawning steelhead populations and to increase basin-wide steelhead productivity by ensuring adequate spawning escapements of the appropriate localized stocks. Specific research activities would be subject to approval of the HCP Hatchery Committees prior to implementation of the research. A representative from NMFS is on each HCP Hatchery Committee to ensure the activities conducted are consistent with steelhead recovery and do not impose substantial risks to protected species. Studies, either ongoing and currently covered under existing permits, or newly proposed studies may include the investigations provided in Table 1.

Table 1. Proposed activities that would be conducted if Permits 1395, 1396, and 1412 are issued.

Type of Activity	Permit 1395	Permit 1396	Permit 1412
Adult Return Monitoring	Intercept and collect biological data (length, scales, marks, tags, etc.) on 10 percent of run Externally tag sampled steelhead Summarize, assess, and report data collected	Not applicable	Not applicable
Adult Return Management	Ensure the run can fully seed the habitat in each basin Develop broodstock collection protocols Determine if excess hatchery steelhead should be removed from spawning populations in each basin	Not applicable	Not applicable
Artificial Propagation	Collect up to 442 broodstock fish at Wells Dam on the Columbia River for Methow and Okanogan Basin releases Collect up to 208 broodstock fish at Dryden and Tumwater Dams for Wenatchee Basin releases		Collect up to 16 adult steelhead for broodstock from Omak Creek or Okanogan River
	Holding and artificial spawning of broodstock at Wells and Eastbank Fish Hatcheries		Holding and artificial spawning of broodstock at Colville Trout Hatchery
	Transfer of 125,000 eyed-eggs or fry from Wells Fish Hatchery to Winthrop National Fish Hatchery annually	Receive up to 125,000 eggs or fry from WDFW annually	
	Transfer up to 225,000 eyed-eggs from Wells Fish Hatchery to WDFW facilities for release from Ringold Springs Rearing Facility annually		
	Incubation and rearing to smolt	Incubation and rearing to smolt	Incubation and rearing to smolt
	Rear juveniles following routine fish culture methods to an average size of 5 to 8 fish per pound	Rear juveniles using routine fish culture methods to an average size of 5 to 8 fish per pound	Rear juveniles using routine fish culture methods to an average size of 5 to 8 fish per pound
	Externally mark or tag all fish prior to release	Adipose fin clip all fish prior to release	Externally mark or tag all fish prior to release

Type of Activity	Permit 1395	Permit 1396	Permit 1412
	Internally tag some smolts prior to release Release up to 180,000 smolts into the Columbia River from Ringold Springs Rearing Facility Release of 350,000 smolts into the Methow and/or Okanogan Basins annually and release of 400,000 smolts into the Wenatchee Basin annually	Release of up to 100,000 smolts in the Methow River annually	Release of up to 40,000 smolts into the Okanogan Basin annually
Research, Monitoring and Evaluation	Investigate the factors that affect and the extent of residulization of juveniles from release groups Determine the relative success of program steelhead in the natural environment Investigate the efficacy of hatchery programs in rebuilding self-sustaining populations Monitor the affect of artificial propagation on the genetic profile of the stocks		Investigate the efficacy of hatchery programs in rebuilding self-sustaining populations Cap a portion of the redds deposited in Omak Creek to determine spawning success of artificially propagated fish in the natural environment Monitor the affect of artificial propagation on the genetic profile of the stocks

2.3.2 Permit 1395 Terms and Conditions

NMFS proposes to issue section 10(a)(1)(A) permit 1395 jointly to the WDFW, the Chelan PUD, and the Douglas PUD with terms and conditions. Specifically, the conditions are designed to minimize ESA-listed fish mortalities and adverse impacts during: the interception and release of Upper Columbia River steelhead adults at Priest Rapids Dam, collection of broodstock from the Columbia River and its tributaries, rearing of juveniles in a hatchery environment, and release of smolts into the Upper Columbia River Basin to enhance the naturally spawning population. Of primary concern in the development of the conditions for the proposed permit is the necessity to take special measures to avoid adverse impacts from artificially propagated returning adult steelhead in years when adequate numbers of natural-origin steelhead escape to the spawning grounds. In years of low natural-origin steelhead returns, the primary objective would be to fully utilize the available habitat while maintaining the genetic integrity of the populations and rebuilding the steelhead resources throughout the ESU. A summary of the terms and conditions that would be placed in the permit is provided in Table 2 (for a complete list of conditions see the draft Permit #1395 and draft Opinion (NOAA Fisheries 2003)).

Table 2. Terms and conditions that would be included in Permits 1395, 1396, and 1412 if issued.

Type of Activity	Permit 1395	Permit 1396	Permit 1412
Adult Return Monitoring	Biological sampling of steelhead at Priest Rapids Dam would be conducted on a random sample targeting 10 percent of the total run. ESA-listed fish handled out of water must be anaesthetized and allowed to recover before release External tags may be applied only to adipose fin clipped steelhead sampled after September 9th Data would be summarized, assessed and reported weekly including direct and indirect mortalities	Not applicable	Not applicable
Adult Return Management	Priority would be given to fully seeding the habitat with natural origin steelhead in each basin Broodstock collection protocols would be developed annually and submitted to NMFS Determination of potential benefits of removing excess hatchery steelhead from the spawning population would be done separately for the Wenatchee, Methow, and Okanogan Basins	Not applicable	Not applicable
Artificial Propagation	The permit holders would reduce potential negative impacts to listed salmon and steelhead in the upper Columbia River Basin from physical operation of their respective artificial propagation facilities, including associated trapping locations		
	Steelhead captured for broodstock would be removed from traps daily	Not applicable	Steelhead captured for broodstock would be removed from traps daily
	Fish not retained for broodstock would be released upstream of the trap immediately after enumeration	Not applicable	Fish not retained for broodstock would be released upstream o the trap immediately after enumeration
	Artificial propagation production levels would not exceed those in the application documents without further consultation with NMFS		

Type of Activity	Permit 1395	Permit 1396	Permit 1412
	Incidental mortalities associated with capturing, handling, and transporting broodstock would not exceed 5 percent of the total number of steelhead retained	Not applicable	Incidental mortalities associated with capturing, handling, and transporting broodstock would not exceed 5 percent of the total number of steelhead retained
	If total eyed egg-to-release mortality exceeds 20 percent or a single mortality event exceeds10 percent of the population, then NMFS would be notified within 48 hours of the mortality event		
	Steelhead smolts would be released at an average size of 5 to 8 fish per pound with a length coefficient of variation not to exceed 10 percent		
	Juvenile steelhead would be externally marked prior to release (for example adipose fin clip or visual elastomer tag)	Juvenile steelhead would be adipose fin clipped prior to release	Juvenile steelhead would be externally marked prior to release (for example adipose fin clip or visual elastomer tag)
	A portion of the juvenile steelhead may be internally tagged prior to release (for example coded-wire tag (CWT) or passive integrated transponder (PIT) tag		
	Up to 180,000 smolts would be released into the Columbia River from Ringold Springs Rearing Facility		
	Up to 350,000 smolts would be released into the Methow and/or Okanogan Basins annually	Release of up to 100,000 smolts in the Methow River annually	Release of up to 40,000 smolts into the Okanogan Basin annually
	Up to 400,000 smolts would be released into the Wenatchee Basin annually		
	Annual reports would be submitted to NMFS that include a summary of artificial propagation program activities including broodstock characteristics (for example natural or hatchery origin, sex, age, length, fecundity, mating strategy), rearing conditions (for example water temperature and sources), biological data collected (for example growth rates, health condition monitoring), numbers and types of external and internal mark and tags, description of studies and/or rearing comparisons, release summaries, and other information pertinent the evaluation of the specific broods year or group artificially propagated at each facility		
Research, Monitoring, and Evaluation	The permit holders would monitor and report the contribution of adult salmon from the artificial propagation programs authorized in this permit. Adult return information should include the most recent estimates of the number and proportion of artificially propagated fish on the spawning grounds, and the number and location of artificially propagated adults that were recovered outside the release areas		

Type of Activity	Permit 1395	Permit 1396	Permit 1412
	Visual observation protocols would be used instead of intrusive sampling methods whenever possible Each ESA-listed fish handled out-of-water would be anesthetized when necessary to prevent injury or mortality. Anesthetized fish would be allowed to recover (e.g., in a recovery tank) before being released. Fish that are simply counted would remain in water but would not need to be anesthetized The permit holders would be responsible for any biological samples collected from ESA-listed species as long as they are useful for research purposes. The terms and conditions concerning any samples collected under this authorization would remain in effect as long as the permit holders maintains authority and responsibility of the material taken. The permit holders may not transfer biological samples to any persons, agencies, organizations or any other entity not listed in the application without obtaining prior written approval from NMFS		

2.3.3 Permit 1396 Proposed Artificial Propagation Activities

Winthrop National Fish Hatchery is located near Winthrop, Washington on the Methow River, above its confluence with the Columbia River. Total distance from the hatchery to the Pacific Ocean is 568 river miles, and nine hydroelectric dams are located within the migration corridor. Production goals at Winthrop National Fish Hatchery were set by the Columbia River Fisheries Management Plan under *U.S. v. Oregon* (USFWS 2002). The current steelhead program at Winthrop National Fish Hatchery of 100,000 summer steelhead smolts annually started in 1995 with eyed eggs being transferred and fry brought to the station from Wells Fish Hatchery in 1996.

This permit application, proposed for a 10-year period commencing in 2003, addresses listed steelhead artificial propagation at Winthrop National Fish Hatchery. Adult steelhead within the Upper Columbia ESU would be intentionally taken at Wells Fish Hatchery by WDFW and eyed eggs or fry transferred to Winthrop National Fish Hatchery to be reared and released by the USFWS for the purpose of enhancing the population status of the species through artificial propagation at this facility. Activities that would lead to the take of the ESA-listed species are listed in Table 1.

2.3.4 Permit 1396 Terms and Conditions

NMFS proposes to issue section 10(a)(1)(A) permit 1396 to the USFWS with conditions. Specifically, NMFS' conditions are designed to minimize ESA-listed fish mortalities incidental to the rearing and release of artificially propagated steelhead smolts into the Methow River to enhance the naturally spawning population, and associated scientific research and monitoring activities. Of primary concern in the development of the conditions for the proposed permit is the necessity to take measures to avoid adverse impacts from artificially propagated returning adult steelhead in years when adequate natural-origin steelhead escape to the spawning grounds in order to preserve the genetic and life history characteristics of the ESA-listed species. A summary of the terms and conditions that would be placed in the permit is in Table 2 (for a complete list of conditions see the draft permit 1396 and Opinion (NOAA Fisheries 2003)).

2.3.5 Permit 1412 Proposed Artificial Propagation Activities

NMFS proposes to issue section 10(a)(1)(A) permit 1412 to the Colville Tribes to carry out a artificial propagation program of endangered Upper Columbia River steelhead. The Colville Tribes request a 5-year authorization to utilize artificial propagation techniques to enhance the natural origin Upper Columbia River steelhead in the Okanogan River Basin. Program details were provided in the permit application (CCT 2002) and are summarized in Table 1.

The Colville Tribes propose to install a temporary picket weir in Omak Creek in Mid-March through April 30th annually at approximately RM 0.5 to collect about 16 adult steelhead for broodstock. If the picket weir is not successful, then trap nets or angling would be used to collect

broodstock. The broodstock would be transported approximately 35 miles in a tank truck to the Colville Tribal Trout Hatchery, near Bridgeport, Washington.

Adult steelhead would be spawned and biologically sampled according to standardized fish health practices following fish disease control guidelines developed by Integrated Hatchery Operations Team and the Pacific Northwest Fish Health Protection Committee. Fin tissue, and other biological data would be collected from the broodstock to monitor the program impacts.

Eggs would be incubated and juvenile fish reared at the tribal facility until the yearling smolt stage. Fish health would be monitored routinely, generally on a monthly schedule and the rearing facility would be operated to be in compliance with "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" standards (NWIFC and WDFW 1998). Juvenile fish would be biologically sampled in the hatchery facility including collection of fin tissue for genetic monitoring and growth monitoring.

Juvenile steelhead would externally marked with visual implant elastomer tags for identification purposed but not adipose fin-clipped. Juveniles may also receive passive integrated transponder (PIT) tags for identification purposes. Steelhead smolts with a demonstrated preparedness for downstream migration would be released into Omak Creek from a Natural Rearing Enhancement System (NATURES) type acclimation pond, which is in development with a completion target date of spring 2004, or scatter planted from a tank truck in April or May.

2.3.6 Permit 1412 Terms and Conditions

NMFS proposes to issue section 10(a)(1)(A) permit 1412 to the Colville Tribes with conditions. Specifically, NMFS' conditions are designed to minimize ESA-listed fish mortalities incidental to the capture, handing, transport, spawning, juvenile rearing, and release of artificially propagated steelhead smolts into Omak Creek to enhance the naturally spawning population, and associated scientific research and monitoring activities. Of primary concern in the development of the conditions for the proposed permit is the necessity to take measures to avoid adverse impacts from artificially propagated returning adult steelhead in years when adequate natural-origin steelhead escape to the spawning grounds in order to preserve the genetic and life history characteristics of the ESA-listed species. A summary of the terms and conditions that would be placed in the permit is in Table 2 (for a complete list of conditions see the draft permit 1412 and Opinion (NOAA Fisheries 2003)).

2.3.7 Incidental Take

In addition to direct take, incidental takes of ESA-listed species other than targeted steelhead associated with broodstock collection activities, hatchery operations, and juvenile fish releases from the program would be authorized under the proposed action. Because of the inherent biological attributes of aquatic species such as salmon and steelhead, the dimensions and variability of the Columbia River system and tributaries, and the operational complexities of hatchery actions, determining precise incidental take levels of ESA-listed species attributable to hatchery activities are not possible at present. In the absence of quantitative estimates of incidental take, NMFS would monitor fish release numbers/locations and hatchery operations to assure that incidental takes do not operate to the disadvantage of ESA-listed species. If NMFS determines that incidental take due to the hatchery activities have the potential to operate to the disadvantage of ESA-listed species, the activities that result in the incidental takes must be suspended until a reasonable solution is achieved, the permit is amended, and/or the program is reevaluated under Section 7 of the ESA.

3 AFFECTED ENVIRONMENT

The alternatives identified above can potentially affect the physical, biological, and socioeconomic resources within the action area. The following is a summary of the major components of the environment that would be affected by any of the alternatives and the current baseline condition organized by the type of environment. A full discussion of the environmental baseline can be found in the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002).

3.1 Physical Environment

The proposed action of permitting artificial propagation activities can effect the physical environment by impacting the water quantity, water quality, and the riparian habitat.

3.1.1 Water Quantity

Water quantity can be altered by water withdrawals from a river or stream for use in the artificial propagation facility. The Columbia River average annual flow at Rock Island Dam is 117,737 cubic feet per second (cfs). The artificial propagation programs at Wells and Chelan Fish Hatcheries utilize about 24 and 11 cfs from the Columbia River, respectively. The Wenatchee River watershed is the third largest mid-Columbia River tributary and has an annual discharge of 2.3 million acre-feet (NOAA Fisheries 2002). Average annual flow of the Wenatchee River is 3,304 cfs (years 1963 to 2000) measured at Monitor, Washington. A total of 420 cfs have established water rights, with 3 percent utilized by artificial propagation facilities. Average annual flow from the Methow River at Pateros is 1,579 cfs (years 1963 - 2000). The Washington Department of Ecology estimates that irrigation ditches remove about 50 percent of the river flow in late summer and fall, with 90 percent of that withdrawal being utilized for irrigating agricultural land. The USFWS Winthrop National Fish Hatchery uses up 50 cfs of Methow

River water for both the spring chinook and steelhead artificial propagation programs. Average annual flows in the Okanogan River at Malott, Washington is 3,134 cfs (years 1966 -2000).

3.1.2 Water Quality

Current water quality classification by the Ecology following water quality standards as defined by Chapter 173-201A of the Washington Administrative Code (WAC), indicates that the Columbia River in the action area is relatively unpolluted and has few sources of wastewater or other pollution. However, based on the Army Corp of Engineers and Ecology monitoring, the middle Columbia River region was placed on the 303(d) list for total dissolved gas, water temperature, pH, and a water column bioassay (NOAA Fisheries 2002). Water quality in the Wenatchee River is generally good; however, the river was placed on the 303(d) list for temperature, pH, and dissolved oxygen. The Methow River water quality is also generally good; however, the river was placed on the 303(d) list for temperature and instream flow. The Okanogan River is on the 303(d) list for dissolved oxygen, temperature, and fecal coliform organisms. A thorough discussion of the water quality of the middle and upper Columbia River and the tributaries are described in Chapter 3 of the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002).

3.1.3 Riparian Habitat

The Upper Columbia River Basin flood plain and the foothills of the Cascade Mountains are primarily within the big sagebrush/blue bunch wheat grass or shrub-steppe vegetation zone, which is characteristic of the driest portions of the Columbia Basin physiographic province (NOAA Fisheries 2002). Tributaries in the action area pass through a variety of vegetation zones including forested low-montane zones - dominated ponderosa pine, Douglas fir, and grand fir; and subalpine zones - dominated by lodgepole pine, Engelmann spruce and subalpine fir. Human occupation and land use occur throughout the action area. Riparian habitat may benefit from marine derived nutrients released from decomposing steelhead carcasses that result from artificially propagated steelhead, and their descendants, that spawn and die in the natural environment.

3.2 Biological Environment

The biological resources that potentially could be affected by the proposed action include salmon, steelhead, trout, and other aquatic and terrestrial species. A detailed discussion of the biological resources found in the action area is presented in the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002). The specific resource segments and baseline condition that may be affected by the proposed artificial propagation programs are described below.

3.2.1 Anadromous Fish Listed Under the ESA

Since 1991, NMFS has identified twelve populations of Columbia River Basin anadromous salmon and steelhead as requiring protection under the ESA. The biological attributes of salmon and steelhead, the dimensions and variability of the Columbia River system, and the natural cycles in the ocean environment make determination of the effects from the proposed artificial propagation activities downstream of the action area very difficult. Most of the species interact with fish that would be produced by the proposed artificial propagation activities in the migration corridor and the ocean environments. However, as discussed in Section 1.3 (Action Area) artificially propagated steelhead associated with the proposed programs would comprise only about 1.5 percent of artificially propagated anadromous fish released annually (less than 1.1 million steelhead of 71 million total salmonid releases in 2001) and would be expected to be in the estuary for only a few weeks. Therefore, analysis of impacts of these activities on the biological environment will be limited to the two ESUs expected to be impacted by the proposed action. Both of the ESA-listed ESUs include some portion of artificially propagated fish as well as the naturally spawning populations.

3.2.1.1 Upper Columbia River Spring Chinook

The Upper Columbia River spring chinook salmon ESU was listed as endangered on March 24, 1999 (64 FR 14308). This ESU includes stream-type spring chinook salmon populations originating from all areas of the Columbia River basin upstream of Rock Island Dam (Myers *et al.* 1998). Production areas include the Wenatchee, Methow, and Entiat River Basins. The WDF *et al.* (1993) identified nine stocks within this ESU. All stocks, with the exception of the Methow stock, were considered by the WDF *et al.* (1993) to be of native origin, of "wild" production type, and as "depressed" in status. The Methow River spring chinook salmon stock is considered to be "composite" in production type, but of native origin, and depressed in status. When listing the Upper Columbia River spring chinook salmon as endangered, NMFS included six populations which have been artificially propagated in recent years as part of the ESU: Chiwawa River, Methow River, Twisp River, Chewuch River, White River, and Nason Creek. These six artificially propagated populations were considered to be essential for recovery and were therefore listed as part of the ESU. Artificially propagated populations at Winthrop National Fish Hatchery, Entiat National Fish Hatchery, and Leavenworth National Fish Hatchery were not included as part of the ESU because they were derived from Carson National Fish Hatchery spring chinook salmon.

Upper Columbia River spring chinook salmon have a stream-type life history. Spring chinook salmon destined for the Upper Columbia River and tributaries begin entering the Columbia River in late February and early March, with approximately 50 percent passing Priest Rapids Dam by mid-May. Fish enter the Methow River from mid-May through July and primarily use the upper mainstem reaches of the Methow, Chewuch, Lost, and Twisp Rivers. Spawning occurs from late July through mid-September; fry emerge from the gravel in April and May. Juveniles spend the next year in fresh water prior to migrating downstream in the spring. Spring chinook salmon returning to the Wenatchee River have similar run timing with spawning starting about the second week of August and peaking in the first week of September. Spawning time is dependant on water temperature and generally begins when water temperatures are between 42.4°F and

57.5°F (Mullen 1987 in WDW *et al*. 1990a). Fry emerge from the gravel in January to February and rear in freshwater for up to a year prior to outmigrating during the following spring.

Recent year (1990-95) mean escapement for Upper Columbia River spring chinook salmon was estimated to be 4,880 (Myers *et al.* 1998). Estimates of recent annual trends in abundance were found by NMFS to be downward, with eight of the nine spring chinook populations exhibiting rates of decline exceeding 20% per year. Record low returns were experienced in the middle 1990s. For the Upper Columbia River spring chinook salmon ESU as a whole, NMFS estimates that the average population growth rate (lambda) over the base period ranged from 0.87 to 0.78, decreasing as the effectiveness of hatchery fish spawning in the wild increases compared to that of fish of natural origin (Appendix B in McClure *et al.* 2000) (an annual average growth rate above 1.0 represents a population that is not declining). The estimated average population growth rates and the risk of absolute extinction within 24 and 100 years for the three spawning populations identified by Ford *et al.* (2001), using the same range of assumptions about the relative effectiveness of hatchery fish.

Wenatchee River adult spring chinook returns rebounded in 2000 from low returns observed in 1999. In 2000, an estimated 350 redds were counted in the basin, an almost seven-fold increase from the 54 redds observed in 1999. The greatest increases were seen in Nason Creek, Chiwawa River and the upper Wenatchee River. The 2001 return of naturally produced spring chinook to the Wenatchee River was estimated to be between 640 and 1,052 adults with an additional 438-696 hatchery spring chinook returning to the Chiwawa River. The increased returns in 2000 and 2001 are likely the result of favorable out migration conditions and ocean rearing environment.

Factors for decline in the Upper Columbia River Region, include hydropower facilities and habitat destruction as the major causes of population declines, although past over-harvest in fisheries, and some hatchery practices are other factors. To these factors for decline are added poor ocean conditions prior to 2000, that have suppressed fish survival, and vastly increased avian predation in the Columbia River estuary. These latter factors affect all of the Basin's salmon and steelhead populations.

3.2.1.2 Upper Columbia River Steelhead

The Upper Columbia River steelhead ESU was listed as endangered on August 18, 1997 (62 FR 43937). This ESU inhabits the Columbia River and tributaries upstream of the Yakima River. It includes rivers mostly draining the east slope of the Cascade Mountains. This area includes several rivers which originate in Canada, but it is not thought that steelhead ever occurred in Canada in large numbers; this ESU is defined to include only U.S. populations. This entire ESU has been heavily influenced by artificial propagation programs, with a thorough mixing of stocks as a result of the Grand Coulee Fish Maintenance Project beginning in the 1940s (Fish and Hanavan 1948; Mullan *et al*. 1992). Until recently, hatchery releases were composed of a composite of basin stocks. The Wells Fish Hatchery stock is included in the listing because it may retain the genetic resources of the original steelhead populations about Grand Coulee Dam (62 FR 43937) and may be used for recovery purposes. Currently, efforts are underway to develop artificial propagation programs from more locally-adapted stocks, incorporating some natural-origin steelhead into the broodstock. Steelhead juveniles released into the Wenatchee

River have been progeny of broodstock collected from the Wenatchee River exclusively since the 1998 brood (WDFW 2002).

The life history of this ESU is similar to other inland steelhead ESUs. However, smolt ages in this ESU are some of the oldest on the west coast (up to 7 years old), likely as a result of the ubiquitous cold water temperatures (Mullan *et al*. 1992). Adults of this ESU spawn later than most downstream populations. Adults primarily return after one year of ocean residency. Steelhead from this ESU enter the lower Columbia between May and September with fish arriving at Wells Pool in early July. Fish enter the Wenatchee and Methow Rivers in mid-July and peak between mid-September and October. During winter, fish generally return to the warmer Columbia River and re-enter the Methow to begin spawning in mid-March after ice-out. Spawning continues through May and many fish seek out higher reaches in the tributaries. Fry emergence occurs that summer and juveniles rear for two to four years prior to spring downstream migration.

Although runs during the period 1933 through 1959 may have already been affected by fisheries in the lower river, dam counts suggest a pre-fishery run size of more than 5,000 adults above Rock Island Dam. The return of Upper Columbia River natural-origin steelhead to Priest Rapids Dam declined from a 5-year average of 2,700 beginning in 1986 to a 5-year average of 900 beginning in 1994. Recent escapements at Priest Rapids Dam of both hatchery and natural-origin steelhead have shown an increasing trend reaching 11,330 in 2000, a peak of 30,077 in 2001, and an estimated 15,898 in 2002. Natural origin steelhead returns were estimated at 2,341, 5,715, and 3,013 in 2000, 2001, and 2002, respectively.

In the Upper Columbia River Region, hydropower facilities and habitat destruction are the major causes of population declines, although past over-harvest in fisheries and some hatchery practices are other factors. To these factors for decline are added poor ocean conditions prior to 2000 that have suppressed fish survival, and vastly increased avian predation in the Columbia River estuary. These latter factors affect all of the basin's salmon and steelhead populations.

3.2.2 Other ESA-listed Fish Species

Another ESA-listed fish species that could be present in the areas where the hatchery activities are proposed to occur is bull trout. Bull trout in the Columbia River basin were listed as threatened on June 10, 1998 (63 FR 31647). The Columbia River population segment encompasses a vast geographic area including portions of Idaho, Montana, Oregon, Washington, and British Columbia. Bull trout are present, and locally common, in most of the habitat occupied by anadromous fish in the upper Columbia River Basin. The WDFW (1997) identified 17 bull trout stocks in the Methow River watershed, most are located in the headwater tributaries. The status of these stocks was listed as unknown except for the Lost River stock which was considered healthy (WDFW 1997). In the Wenatchee River, the WDFW (1997) identified 11 bull trout stocks located in the headwater tributaries, out of these 11 stocks, 4 stocks were identified as being healthy and the remaining seven as unknown.

Bull trout populations are known to exhibit four distinct life history forms: resident, fluvial, adfluvial, and anadromous. Resident bull trout spend their entire life cycle in the same (or nearby) streams in which they were hatched. Fluvial and adfluvial populations spawn in tributary streams where the young rear from 1 to 4 years before migrating to either a lake (adfluvial) system or a river (fluvial) system, where they grow to maturity. Anadromous fish spawn in tributary streams, with major growth and maturation occurring in salt water this form is not present in the Methow and Wenatchee Rivers.

Bull trout spawn from August to November as the water temperatures begin to decline. Depending on water temperature, the fry emerge in 100 to 145 days. Juveniles remain in the substrate for some time after hatching. Fry emerge from the gravel in about April. Bull trout populations are fragmented with may individual populations being isolated in one drainage. The distribution of this species appears to be greatly influenced by habitat components such as water temperature (bull trout prefer colder streams), cover, channel form and stability, substrates and migratory corridors (WDW *et al.* 1990b). Bull trout have complex life stage habitat needs. This species utilize large woody debris, undercut banks, boulders and pools. Altered stream flow can disrupt spawning and channel stability is a large factor in egg survival. It is believed that the migratory bull trout occasionally spawn outside of their own natal area, thus over time the genetics remain stable. Migrating adult bull trout are sometimes encountered at weirs during broodstock collection activities.

3.2.3 Non-listed Fish Species

Approximately 60 other species of fish live in the Columbia River and tributaries. About half are native species primarily of the families Salmonidae, Catastomidae, Cyprinidae, and Cottidae. White sturgeon*, Acipenser transmontanus,* occur in the mainstem Columbia River and feed on detritus found on the bottom of the river. They may incur a negligible benefit from juvenile steelhead from the proposed programs that die and sink during the migration. The Columbia River Basin also supports at least 25 introduced species primarily representing Percidae, Centrarchidae, and Ictaluridae. Most of the introduced species are game fish which may be the targets of fisheries that could incidentally take ESA-listed anadromous salmonids.

3.2.4 Wildlife

Wildlife that inhabit and utilize riparian areas include birds, terrestrial mammals, amphibians, and reptiles. A complete discussion of the species present and their habitat utilization is presented in the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002).

In the upper reaches of the Wenatchee, Entiat, Methow, and Okanogan Rivers, and in the tributaries of these rivers, faster flowing, small streams bordered by riparian forest are present. These upper reaches provide habitat for a variety of riparian forest and stream associated wildlife, such as American dippers (*Cinclus mexicanus*), Steller's jays (*Cyanocitta stelleri*), ruby-crowned kinglets (*Regulus calendula*), and tailed frogs (*Ascaphus truei*). Bald eagles (*Haliaeetus*

leucocephalus) use these watersheds during winter and early spring months. The tributaries of the Wenatchee, Entiat, Methow, and Okanogan Rivers extend into remote areas where species such as bobcats (*Lynx rufus*) and mountain lions (*Felis concolor*) are expected to be more common than in developed areas. These species may feed minimally during limited times of the year on juvenile steelhead after release or on decomposing carcasses of spawned adult steelhead.

3.3 Socioeconomic Environment

A full discussion of the socioeconomic environment can be found in the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002). In general, Chelan, Douglas, and Okanogan Counties are largely rural with relatively small population. Together, the three counties contain just 2.4 percent of the State population while covering 10,010 square miles, or 15 percent of the State. The demographics of Native Americans that fish in the Columbia River include the Colville Tribes, Confederated Tribes and Bands of the Yakama Indian Nation, Confederated Tribes of the Umatilla Indian Reservation, Confederated Tribes of the Warm Springs Reservation, and the Nez Perce Tribe. Of these reservations, only the Colville Tribes Reservation is located within the action area.

Historically, natural resources have been the mainstay of the economies of the Native Americans in the Columbia Basin. Hunting, fishing, and gathering are activities that have been important to Tribes for thousands of years. These activities not only continue to be important economically, but also for subsistence and ceremonial purposes. Today, the natural resource portion of the affected Tribal economies, which constitutes 8 percent of the total employment, is made up of fishing, agriculture, food processing, forestry/timber production and wood processing, livestock grazing, and power production. Fishing is the main Tribal industry that would be most affected by the proposed activities.

In 2000, the various Tribes landed 52,419 chinook salmon, 15,540 steelhead, 6,299 coho salmon, and 3,447 sturgeon during the commercial fishing season in the lower Columbia River (Joint Columbia River Management Staff 2001). The commercial fishery represents an important part of the economies of the five Tribes. Estimates of the Tribal salmon fishery in Washington were valued at almost $7 million in 1997 (Tiller and Chase 1999). However, over time, there has been a substantial decline in salmon stocks, and this decline has affected the economies of the project area Tribes. The subsistence fish harvest for the four Treaty Tribes includes the fish species listed above and also includes sockeye and spring- and summer run chinook salmon. In 2000, the Treaty Tribes caught 14,635 fall-run, 11,250 spring-run, and 280 summer-run chinook salmon, 6,628 steelhead, 2,765 sockeye salmon, 1,884 coho salmon, and 324 sturgeon, for subsistence or ceremonial purposes (NOAA Fisheries 2002).

In recent years, with salmonid numbers severely reduced due primarily to habitat degradation and hydropower development in the mainstem river, commercial and recreational fisheries have been considerably curtailed from earlier levels. Currently, harvest is not considered to be as great a source of salmonid population decrease as habitat degradation and hydropower projects. Harvest

rates are managed at conservative levels until improvements in other sectors of the environment are able to take effect.

Numerous jobs are indirectly (for example, commercial fishers and retailers) and directly (for example, fish culturalists and fish managers/regulators) associated with or affected by the proposed artificial propagation programs and the listing of the species under the ESA. In addition to their role in maintaining the viability of salmonid populations, the artificial propagation programs contribute fish to recreational, commercial, and tribal fisheries throughout the Columbia River Basin.

Natural and hatchery-origin steelhead continue to play an important role for Native American cultural, religious, subsistence, and commercial purposes in the action area. The current depressed status of listed spring chinook salmon and steelhead populations has severely limited many of the cultural practices and subsistence uses of salmon by the local tribes. The poor status of the listed populations has also curtailed economic and cultural benefits for non-Indian recreational fisheries that the steelhead resource formerly supported.

4 ENVIRONMENTAL CONSEQUENCES

The proposed action can potentially affect the physical, biological, social, and economic resources within the action area. The following is an analysis of the potential environmental consequences on the major components of the environment based on the current baseline condition described in Section 3 (Affected Environment), above, organized by the alternatives considered in Section 2 (Alternatives Including the Proposed Action). Please see the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002) for more detail of the environmental consequences of the three HCPs.

4.1 Alternative 1 - Do Not Issue Permits (No Action)

Under this alternative, the artificial propagation programs would not be operated as described.

4.1.1 Effects On the Physical Environment

The No Action alternative would not substantially change the magnitude or type of effects on the physical environment. The cessation of the proposed ESA-listed steelhead artificial propagation programs would not necessarily decrease impacts on the physical environment because the activities of artificially propagating unlisted salmon would continue and potentially be increased. The cessation of the steelhead program could result in loss of beneficial nutrient flow into the upper tributaries and spawning grounds. Specific considerations of effects on water quality, water quantity, and riparian habitat are described below.

4.1.1.1 Water Quantity

Production capacity at hatchery facilities would most likely be used to rear non-listed salmon species or listed spring chinook salmon. If this occurred, surface water withdrawals are likely to not change from the existing level. Water diversions at trapping facilities are minimal and trapping periods for other propagated species overlap (i.e., summer chinook and coho) much of the steelhead trapping period. Therefore it is unlikely a substantial change, either positive or negative would occur.

4.1.1.2 Water Quality

As described above, the total artificial production capacity of the hatchery facilities would likely not change. An increase in production of unlisted salmon would likely occur to fill the vacancy created by the cessation of the steelhead programs. Therefore, the impacts under this alternative would not be expected to result in any change from current baseline conditions.

4.1.1.3 Riparian Habitat

Small localized impacts at trapping sites might be reduced from the current level because steelhead broodstock collections would be discontinued at the remote locations, but because trapping periods of other propagated species overlap much of the steelhead trapping period, the reduced impacts would likely be negligible. The discontinuation of steelhead smolt releases from tank trucks could result in minor reductions of impacts at the release sites. The reduction in steelhead returns may result in negative impacts to the environment by decreasing the amount of marine derived nutrients that would have been released into the watershed from artificially propagated carcasses.

4.1.2 Effects On the Biological Environment

The biological environment considered in this EA includes ESA-listed anadromous fish species, other ESA-listed fish species, non-listed fish species, and wildlife.

4.1.2.1 Anadromous Fish Listed Under the ESA

Under the No Action alternative, annual takes of endangered Upper Columbia River steelhead associated with artificial propagation programs would not be authorized. To meet production goals in the Wenatchee, Methow, and Okanogan Rivers artificial propagation programs, under the proposed alternative, about 650 adult ESA-listed steelhead are needed for broodstock. If the program is discontinued, the 650 steelhead that would have been collected would be allowed to spawn naturally during the initial few years without hatchery production.

NMFS has concluded that the Upper Columbia River steelhead species is at risk of extinction (62 FR 43937). The risk of extinction and the hazard of the loss of genetic diversity is increased by the extremely low numbers of natural-origin parents in each generation. In years of low survival of natural-origin steelhead, the artificially propagated steelhead would be allowed to spawn naturally and assist in fully seeding the habitat, providing a benefit to the ESU. The benefits of artificially propagated steelhead spawning in the ESU when the natural population is at very low levels include preservation of genetic diversity, and persistence of the species. The long term implications of the cessation of the program would likely include the continued decline of the

species, particularly in the Methow and Okanogan Basins where the current populations are likely heavily represented by artificially propagated steelhead.

Under the No Action alternative, ESA-listed Upper Columbia River spring chinook would not benefit from the restored productivity and increased forage supply that could be provided by a restored steelhead population. Any reduced risk from lack of trapping activities would be negligible since steelhead and spring chinook salmon adult migrations occur during different times of the year. However, impacts may be similar or increased if another non-listed species was produced to replace the production capacity lost under this alternative.

4.1.2.2 Other ESA-listed Fish Species

The discontinuation of the listed steelhead artificial propagation would not likely reduce effects on bull trout. Steelhead trapping generally occurs at locations and times when bull trout are rarely present. Release of effluent and water withdrawal impacts would likely not change from the baseline condition if other species are reared at the hatchery to replace the discontinued steelhead program.

4.1.2.3 Non-ESA-listed Fish Species

The discontinuation of the ESA-listed steelhead artificial propagation program would not be expected to have any impacts on non-ESA-listed fish species because the hatchery facilities would likely increase production of non-ESA-listed species, and the overall impact of hatchery program operation would likely remain consistent with the baseline conditions.

4.1.2.4 Terrestrial Organisms

Without the annual input of artificially propagated steelhead adults and their carcasses in the river environment, terrestrial organisms that feed on live-caught or spawned-out carcasses may by adversely impacted such as bears, river otters, and other terrestrial scavengers. The extent of adverse impacts would be localized in the tributaries, and considering the entire scope of the action area, would likely be minor.

4.1.3 Effects On The Socioeconomic Environment

The No Action alternative would likely result in a decrease in the Upper Columbia River steelhead ESU population size. The risk of extinction or loss of important genetic material would continue or would increase. No fish would be available for treaty tribal ceremonial and subsistence use or for recreational fishing opportunities. Loss of these fishery opportunities would not fulfill tribal trust responsibilities and would potentially negatively impact the local economy because of lost income from local steelhead fisheries in the Upper Columbia River basin. Should the Upper Columbia River steelhead become extinct, the existence value of the species would also be lost. If Upper Columbia River steelhead continue to decline, it would be expected that more restrictions could occur in other areas that affect the species. These additional restrictions could impact water withdrawals for domestic and agricultural uses, grazing, mining, timber harvest, and development within the watersheds.

4.1.4 Environmental Justice

Executive Order 12898 (59 FR 7629) directs federal agencies to identify and address, as appropriate, any disproportionately high and adverse human health or environmental effects on minority populations and low-income populations. The No Action alternative would not be expected affect human health of any population located in the action area.

Under the No Action alternative recreational harvest opportunities for all population segments could be reduced. Tribal harvest and subsistence fishing opportunities, and potential fishing opportunities for low-income persons could be reduced as well, but would not be disproportionately affected under the No Action alternative.

4.2 Alternative 2 - Issue Permits Without Conditions

4.2.1 All Resources

The purpose of permit conditions is to prescribe requirements and/or restrictions that are expressly designed to minimize impacts to ESA-listed fish. Issuing permits and/or permit modifications without conditions would result in many of the same environmental impacts described under the No Action alternative because, as previously described, the proposed ESA-listed steelhead artificial propagation programs would likely be replaced by non-ESA-listed propagation programs. The impacts would likely also be similar to the impacts under the proposed alternative described below in Section 4.3 (Alternative 3 - Issue Permits With Conditions) because many of the techniques that result in permit conditions are provided as proposed strategies in permit applications. However, not imposing conditions in permits could potentially result in unexpected environmental impacts if impact minimization strategies are substantially altered or are not implemented by the permit holders. Establishing conditions in permits ensures that measures would be implemented by the permit holders to minimize adverse impacts to ESA-listed fish and that the actions of the agencies and tribes would not appreciably reduce the survival and recovery of ESA-listed species. In addition, NMFS' conditions may serve to further limit activities in such a way as to enhance the proposed conservation efforts. The effects of this alternative on the human environment would nominally be the same as under the proposed action, but the certainty of these actions would be unpredictable.

4.3 Alternative 3 - Issue Permits With Conditions (Proposed)

Under this alternative the proposed artificial propagation programs of ESA-listed Upper Columbia River steelhead would be operated as previously described in Section 2.3 (Alternative 3 - Issue Permits with Conditions) and subject to terms and conditions as required under section 10 of the ESA. The possible impacts to the physical, biological, and socioeconomic environments are described in this section. Please see the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002) for an in depth discussion of the ramifications of implementing the three HCP agreements.

4.3.1 Effects on the Physical Environment

The effects on the physical environment resulting from implementation of the proposed artificial propagation program could include impacts on water quantity, water quality, and riparian habitat. However, any impact would likely be minimal, occur in a small areas within the entire action area, and would not be substantial. Specific considerations of potential impacts on the physical environment by the proposed action are described below.

4.3.1.1 Water Quantity

To limit impacts on water quantity, the permit holders would comply with water right permits established for each hatchery to prevent over-appropriation of surface water. The hatchery facilities considered in this EA utilize a small portion of the total water allocation in each affected river (3 percent of the total water allocation in the Wenatchee River, and about 3 percent of the total average flow in the Methow River); furthermore, the steelhead programs use only a portion of the total water allocation for each facility. No change of the amount of available water would be expected. Water would be returned to the river of origin near the withdrawal point. All impacts would be similar to those described under the No Action alternative.

4.3.1.2 Water Quality

While water quality may be effected by effluent from the artificial propagation activities, all the hatchery facilities would be required to operate under National Pollutant Discharge Elimination System (NPDES) permits issued by the Washington Department of Ecology. Hatchery effluent standards and point source discharge criteria are set forth in the permit to protect aquatic life and the habitat in the area below the discharge points. To monitor water quality and the impacts of hatchery effluent, the facility operators monitor total suspended solids, settleable solids, upstream and downstream temperatures, and upstream and downstream dissolved oxygen. Considering that the effluent produced from the hatchery facilities complies with Environmental Protection Agency standards, coupled with the low percentage of effluent to discharge (dilution factor), there is a low possibility that effluent produced at these facilities would negatively impact the physical environment regardless of species of fish is being reared. Under the proposed alternative in which ESA-listed steelhead are propagated, the impact would not be expected to be different than the impacts described under the No Action alternative.

4.3.1.3 Riparian Habitat

Small localized impacts at trapping sites might be incurred because steelhead broodstock would be collected at the remote locations, but because trapping periods of other propagated species (i.e., summer chinook and coho) overlap much of the steelhead trapping period, the additional impacts would likely be negligible. The release of steelhead smolts from tank trucks could result in minor, short-term impacts at the release sites. Some additional marine derived nutrients may result from the hatchery carcasses, however, in the near-term the nutrient input would be negligible.

Possible impacts on riparian habitat and associated vegetation would occur primarily through activities directly related to the facilities used for trapping and rearing ESA-listed fish and the maintenance and repair of existing facilities. Existing hatchery facilities and traps would be

utilized to carry out the proposed activities. Therefore, effects are not likely to differ substantially from those under the No Action alternative.

4.3.2 Effects On the Biological Environment

The biological resources that may be affected include both ESA-listed and unlisted anadromous fish species, freshwater fish species, and terrestrial organisms. Impacts on these resources are described in the following section.

4.3.2.1 Anadromous Fish Listed Under the ESA

The expected impacts on anadromous ESA-listed fish species in the Upper Columbia River Basin from the proposed artificial propagation program would mainly be limited to steelhead in the Wenatchee, Methow, and Okanogan River drainages. The other anadromous ESA-listed fish species expected to occur in the action area is Upper Columbia River spring chinook salmon.

Upper Columbia River Steelhead: Compared to the No Action alternative, the Proposed Action alternative has the potential to contribute to the long term persistence of ESA-listed Upper Columbia River steelhead. The steelhead artificial propagation programs may be responsible in large part for sustaining the natural production component in the Methow and Okanogan Basins within the ESU (62 FR 43937). Continuation of these programs is likely to continue to contribute to the persistence of the steelhead stock. In carrying out the programs up to 650 adults steelhead would be removed from the run annually compared to the No Action alternative. However, the long-term impacts to the ESA-listed stock would be expected to be an increase in the ESA-listed population. Under this alternative special conditions to ensure the programs are operated to the benefit of the ESA-listed species would occur. Annual limits would be placed on the number of listed steelhead allowed to be collected based on the run composition. Run attributes that would be considered include age at return, sex ratio, and natural-to-hatchery origin ratio. Annual broodstock collection protocols would be developed and approved by NMFS prior to steelhead retention to ensure that the activities do not pose a substantial risk to the recovery of the ESU. While the proposed artificial propagation program has the potential to cause deleterious direct and indirect effects on the ESA-listed species, such as maladaptive genetic, physiological, or behavioral changes in donor or target populations (Hard *et al.* 1992), the program would likely be necessary to prevent the extinction of the ESU until habitat conditions that limit the productivity of naturally-produced steelhead in the region can be improved. Therefore, the program includes elements designed to minimize adverse impacts.

Measures designed to minimize impacts on the ESA-listed species include the use of more than one artificial propagation strategy, annual consideration of run size and composition, measures to purposely manage returning artificially propagated adult steelhead, and long-term monitoring and evaluation of the efficacy of the programs and a means to modify the programs through the HCP Hatchery Committees. When implemented, these measures would help to minimize the risk of genetic and/or ecological hazards to the ESA-listed species.

The proposed programs would collect no more than 650 mixed origin (natural and artificially propagated) adult steelhead annual. In some years, the total broodstock collection goal is likely

to be less, because run composition as determined at Priest Rapids Dam would be considered, and in years of high survival of steelhead that spent two years in the ocean the collection number would be adjusted downward in consideration of the high fecundity of the older fish. The proportion of natural origin steelhead for broodstock would be determined annually, again taking into account the total run composition as determined at Priest Rapids Dam.

Spring chinook: Listed spring chinook return to the Upper Columbia River from April through early July, while steelhead typically return in July through November. The temporal separation reduces the potential for negative impacts to occur. Program operation, such as trapping directed at steelhead would not take place when most of the spring chinook run is present. Native steelhead co-evolved with native spring chinook salmon and would be expected to suffer no negative impacts from the restoration of the steelhead population. ESA-listed steelhead and the ESA-listed salmon population would both be expected to benefit from the recycled marine nutrients added to the ecosystem by natural spawning hatchery fish. The impacts of the Proposed Action alternative would likely be less than the No Action alternative because the No Action alternative could result in an increase of artificial production of other species that could potential interact more directly with ESA-listed spring chinook salmon.

4.3.2.2 Other ESA-listed Fish Species

Bull trout may be present in the waters where the proposed hatchery activities would take place. However, the impacts on threatened bull trout are expected to be negligible and similar to impacts under the No Action alternative. Bull trout are rarely seen in the broodstock collection traps used for steelhead. The WDFW has established specific procedures for handling bull trout when they are encountered, with bull trout being enumerated and released unharmed back into the river. No mortalities are expected under the Proposed Action alternative. Bull trout co-evolved with steelhead, and restoring the fully functional ecosystem would not be expected to have a negative impact. Bull trout are piscivorous and may utilize the additional steelhead eggs, fry, and parr as a forage resource. Bull trout would also be expected to benefit from the recycled marine nutrients added to the ecosystem by natural spawning artificially propagated steelhead.

4.3.2.3 Non-listed Fish Species

Non-listed fish species may be encountered during the operation of the collection traps, and affected by the hatchery effluent and the withdrawal of water. Impacts would be expected to be very small, only slightly greater than under the No Action alternative. Non-listed species that would be encountered during hatchery operations would be released unharmed, and no mortalities would be expected. Non-listed fish species may be affected by hatchery effluent but these effects are limited to the point of release and so would be transitory. Resident fish species would be expected to benefit from the nutrient enrichment and the ecosystem restoration impacts that would occur concurrently with the recovery of the steelhead populations.

4.3.2.4 Terrestrial Organisms

Similar to the No Action alternative, the scale of the proposed artificial propagation program would be relatively small given the geographic region and because it makes use of existing hatchery facilities for the hatching and rearing stages, additional impacts on terrestrial organisms, ESA-listed or unlisted, are not anticipated to be substantial or long-lasting. Additional carcasses

from artificially propagated but naturally spawning steelhead would be added to the environment but, at the level considered here, they would not likely be an important source of nutrients or food for terrestrial organisms.

4.3.3 Effects On The Socioeconomic Environment

The principal impact of the proposed Upper Columbia River steelhead artificial propagation programs would be to restore the opportunity for non-consumptive observation of spawning steelhead and the existence value of the species. Real and sustained increases in salmonid numbers are uncertain, but are not likely to be great over the near-term. The artificial propagation program would be expected to continue into the future as mitigation for the operation of the hydropower projects whose impacts cannot be entirely minimized through design and operational changes.

In years of substantial natural-origin steelhead adult return, the availability of artificially propagated steelhead for ceremonial and subsistence uses by the treaty Indian tribes would increase. In years of low returns of natural-origin steelhead, the artificially propagated steelhead would be allowed to spawn naturally to fully seed the habitat and contribute to the recovery of the listed ESU. In years of high returns of naturally produced steelhead, the artificially propagated steelhead may contribute to tribal and recreational fisheries.

Recreational fishing provides income and employment opportunities in remote, rural communities located in the Columbia River Basin. In 2001, a very high return year in which a limited steelhead harvest on artificially propagated adipose fin-clipped fish was opened, an estimated 2,855 angler trips occurred (memo from H. Bartlett, WDFW, December 9, 2002). It has been estimated that the average angler spends about $34 per trip for salmon and steelhead. This resulted in an estimated benefit of $97,000 to the local economy during the 2001 steelhead fishery. Future local economic benefits could be expected to be similar, but would be widely variable, based on run sizes, and would be considered a positive impact compared to the No Action alternative.

4.3.4 Environmental Justice

Executive Order 12898 (59 FR 7629) directs federal agencies to identify and address, as appropriate, any disproportionately high and adverse human health or environmental effects on minority populations and low-income populations. As under the No Action alternative, the Proposed Action alternative would not be expected to affect human health of any population located in the action area.

Under the Proposed Action alternative increased fishing opportunities may result compared to the No Action alternative for all population segments. Tribal harvest and subsistence fishing opportunities, and potential fishing opportunities for low-income persons could increase, but would not be disproportionately affected.

4.4 Cumulative Effects

Cumulative impacts from NMFS' proposed issuance of the section 10(a)(1)(A) permits, including terms and conditions as described, would be minor if at all measurable. Incremental impacts on the environment are included in the discussion above. NMFS' permitting of the described activities would be only one element of a large suite of regulations and environmental factors that may influence the overall management of artificial propagation actions in the affected environment, and that may impact the health of listed salmon populations and their habitat. For example water quality is monitored and managed through permits from the Washington Department of Ecology. Those programs that meet the requirements of section 10 and its implementing regulations would include monitoring and adaptive management measures so that basin co-managers can respond to changes in the status of affected listed salmon and steelhead. Monitoring and adaptive management would help ensure that the affected ESUs are adequately protected and help counter-balance any negative cumulative impacts.

Other federal, state, and tribal actions are expected to occur within the action area that would increase natural fish populations in the upper Columbia River Basin. Federal actions for salmon recovery in the Columbia Basin currently underway include initiatives by the Northwest Power Planning Council, the Federal Caucus basinwide recovery strategy, and others (NOAA Fisheries 2002). State initiatives include recently passed legislative measures to facilitate the recovery of listed species and their habitats, as well as the overall health of watersheds and ecosystems. Regional programs are being developed that designated priority watersheds and facilitate the development of watershed management plans. Tribes have developed a joint restoration plan for anadromous fish in the Columbia River basin, known as the *Wy-Kan-Ush-Mi Wa-Kish-Wit* or *Spirit of the Salmon* plan. Please see the *Anadromous Fish Agreements and Habitat Conservation Plans Final Environmental Impact Statement for the Wells, Rocky Reach, and Rock Island Hydroelectric Projects* (NOAA Fisheries 2002) for further discussion of anticipated actions in the Columbia River Basin. The cumulative impacts of implementing recovery programs in the upper Columbia River Basin in addition to the three permits reviewed in the EA are expected to increase the production and survival of natural fish in the four tributary basins associated with the proposed programs.

5 AGENCIES CONSULTED

The following agencies and entities were consulted during the development of this environmental assessment.

NOAA's National Marine Fisheries Service
U.S. Fish and Wildlife Service
Washington Department of Fish and Wildlife
Colville Confederated Tribes
Public Utility District No. 1 of Douglas County
Public Utility District No. 1 of Chelan County

7 Finding of No Significant Impact

Summary

NOAA's National Marine Fisheries Service (NMFS) Northwest Region (NWR) has prepared an Environmental Assessment (EA) of its proposed action to issue three permits pursuant to section 10(a)(1)(A) of the Endangered Species Act (ESA) (NOAA Fisheries 2003):

1. Permit 1395 would be issued jointly to the Washington Department of Fish and Wildlife (WDFW), Public Utility District No. 1 of Chelan County, and Public Utility District No. 1 of Douglas County,
2. Permit 1396 would be issued to the U.S. Fish and Wildlife Service (USFWS),
3. Permit 1412 would be issued to the Confederated Tribes of the Colville Reservation (Colville Tribes).

These permits would authorize direct take of listed Upper Columbia River (UCR) steelhead during operation of artificial propagation research/enhancement programs in the UCR Basin. These program are experimental and are designed to determine whether hatcheries can assist in recovering endangered steelhead UCR streams. Permit 1395 provides mechanisms, including recreational harvest, to manage surplus adult hatchery steelhead in specific areas of the basin, and transport of surplus adult hatchery steelhead collected at Ringold Springs Rearing Facility to landlocked ponds and lakes, where they could provide additional harvest opportunity. Permit 1395 would expire on December 31, 2013, and permits 1396 and 1412 would expire on December 31, 2008.

NMFS considered and analyzed the following alternatives, all of which are discussed in detail in the EA:

Alternative 1 - No Action: Do not issue the permits, which would likely require the program operators to cease, or drastically reduce the scope of, the programs.

Alternative 2 - Issue the permit based on the application without any additional specific conditions.

Alternative 3 - Proposed Action: Issue the permits based on the application with additional specific conditions to minimize adverse impacts on the ESA listed salmonids and to enhance conservation efforts.

The proposed action would allow the permit holders to implement artificial production programs that are designed to enhance natural production of ESA-listed UCR steelhead in the Wenatchee, Methow, and Okanogan River Basins in the state of Washington. The programs are fully described in the EA and in the permit application documents.

Issuance of the permits with additional special conditions would be expected to result in the following environmental, social, and economic effects:

- Small, localized, and transitory adverse effects on water quantity and water quality from water withdrawals and hatchery effluent.
- Benefits to the survival and persistence of endangered UCR steelhead.
- Benefits to the knowledge base of artificial propagation as a tool for recovery of depressed and/or threatened and endangered species.
- Potential deleterious effects from artificial propagation such as maladaptive genetic, physiological and behavioral changes, disease transmission and reduction in the number of adults spawning in the wild.
- Few, if any, effects on other ESA-listed species through trapping activities that have the potential to handle listed spring chinook, and bull trout.
- Benefits to listed fish and other resident species from recycled marine nutrients added to the ecosystem.
- Mitigation for continued impacts from the hydro-power system where impacts cannot be minimized through design and operational changes.
- Potential increase in the availability of steelhead for ceremonial and subsistence uses by treaty tribes and the opportunity for recreational fisheries.

These are fully described in the EA.

In the EA, NMFS considered the context and intensity of the factors identified in NOAA NAO 216-6 section 6.01b, as well as short and long term effects of the proposed action. Based on the analysis in the EA, NMFS finds that:

1. Public health and safety will be minimally affected by the preferred alternative. Any degradation of water quality will be restricted to the areas immediately adjacent to hatchery facility water discharges, and any adverse effects will be localized and temporary.

2. The proposed action alternative effects on the human environment are not likely to be highly controversial, based on information provided during the public comment period and the potential benefits to socioeconomic resources expected (as described in the EA).

3. This action does not establish a precedent for future actions with significant effects nor does it represent a decision in principle about a future consideration because NMFS has analyzed many comparable programs and issued many comparable permits.

4. This action is of limited context and intensity, with limited environmental effects, individually or cumulatively.

5. The effects of this action are relatively certain and do not involve unique or unknown risks because this artificial propagation program is similar to other artificial propagation programs designed for research and enhancement of natural production as a means of conservation and recovery of protected populations.

6. The proposed action will not adversely affect areas listed in or eligible for listing in the National Register of Historic Places, or cause loss or destruction of significant scientific, cultural or historic resources.

7. The proposed action will not adversely modify or destroy designated critical habitat as defined by the ESA or designated essential fish habitat (EFH) as defined by the Magnuson-Stevens Act. The artificial propagation programs that are the subject of the proposed action will affect habitat features such as water quality, water quantity, adult passage impediment, predation, competition, and exchange of disease organisms. As discussed in the EA, any adverse effects will by minimal, localized and temporary. The proposed permit conditions and operating procedures are designed to minimize the adverse effects.

9. The proposed action does not threaten a violation of federal, state, or local law requirements imposed for the protection of the environment. To comply with water quality standards, hatchery operators must obtain National Pollutant Discharge Elimination System (NPDES) permits; this requirement is included in the application.

Environmental Justice: Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*. The analysis of the impacts in the EA indicates that there will be no disproportionately high and adverse environmental impacts, as described in the executive order, on minority or low-income populations by the proposed action.

NOAA Fisheries. 2003. Environmental assessment of a National Marine Fisheries Service action to issue three research and enhancement permits under section 10(a)(1)(A) of the Endangered Species Act for artificial propagation of ESA-listed Upper Columbia River steelhead. NOAA Fisheries, Portland, Oregon.

Determination

Based on the analysis in the EA, I conclude that the proposed action to issue permits 1395, 1396, and 1412 with specific conditions pursuant to section 10(a)(1)(A) of the ESA does not constitute a major Federal action significantly affecting the quality of the human environment within the meaning of section 102(2)(c) of the National Environmental Policy Act of 1969 (as amended). Therefore, an environmental impact statement is not required.

Biological Opinions Supporting Incidental Take Permits

Biological Opinion for Permit No. 1347 (2003)

National Marine Fisheries Service Endangered Species Act (ESA) Section 7 Consultation Biological Opinion and Magnuson-Stevens Act Essential Fish Habitat Consultation

Action Agencies:	National Marine Fisheries Service (NMFS) U.S. Fish and Wildlife Service (USFWS) Bonneville Power Administration (BPA)
Evolutionarily Significant Units (ESUs) Affected:	Upper Columbia River (UCR) steelhead (*Oncorhynchus mykiss*) UCR spring chinook salmon (*O. tshawytscha*)
Essential Fish Habitat Affected:	Chinook Salmon
Activities Considered:	1. Issuance of an incidental take statement (ITS) to the USFWS 2. Issuance of an ITS to the BPA and the Confederated Tribes and Bands of the Yakama Nation (Yakama Nation) 3. Issuance of permit 1347 jointly to the Washington Department of Fish and Wildlife (WDFW), the Public Utility District No. 1 of Chelan County (Chelan PUD), and the Public Utility District No. 1 of Douglas County (Douglas PUD)
Consultation Conducted by:	Salmon Recovery Division, Northwest Region Consultation Number 1999/01883

This Biological Opinion (Opinion) constitutes NMFS' consultation under section 7 of the ESA on artificial propagation programs in the UCR basin (1) operated by the USFWS that rear and release unlisted spring chinook salmon, and (2) funded by the BPA and operated by the Yakama Nation for production of unlisted coho salmon (*O. kisutch*). Additionally, it considers NMFS' intention to issue one ESA section 10(a)(1)(B) permit action authorizing incidental take of ESA-listed UCR spring chinook salmon and UCR steelhead by artificial propagation programs for unlisted summer chinook salmon, fall chinook salmon, and sockeye salmon (*O. nerka*) operated by the WDFW, and funded by the Chelan PUD and the Douglas PUD. It has been prepared in accordance with section 7 of the ESA of 1973, as amended (16 U.S.C. 1531 et seq.). It is based on information provided by the USFWS, the BPA/Yakama Nation, the WDFW, the Chelan PUD, the Douglas PUD, published and unpublished scientific information on the biology and ecology of steelhead and spring chinook salmon in the action area, and other sources of information. A complete administrative record of this consultation is on file with the Salmon Recovery Division in Portland, Oregon.

Approved by: D. Robert Lohn, Regional Administrator **Date Issued:** 11/2/03 (**Expires ten years from signing**)

1 INTRODUCTION

This Biological Opinion (Opinion) is the result of an interagency consultation carried out pursuant to section 7(a)(2) of the Endangered Species Act (ESA) and implementing regulations 50 CFR §402 concerning artificial propagation programs located in the upper Columbia River (UCR) basin that rear and release unlisted spring chinook salmon, summer chinook salmon, fall chinook salmon, coho salmon, and sockeye salmon. This Opinion considers the effect of facilities operations, juvenile releases, adult collection, related monitoring and evaluations, and related research projects on ESA-listed species of anadromous salmon and steelhead in the Columbia River basin. The federal agencies that fund and/or operate hatcheries, namely the U.S. Fish and Wildlife Service (USFWS), and the Bonneville Power Administration (BPA), have initiated consultation with National Marine Fisheries Service (NMFS) on operation of the federal hatchery programs. In addition, NMFS is consulting with itself on its proposed issuance of an incidental take permit (1347) for hatchery programs implemented jointly by the Washington Department of Fish and Wildlife (WDFW) , the Public Utility District No. 1 of Chelan County (Chelan PUD), and the Public Utility District No. 1 of Douglas County (Douglas PUD) pursuant to section 10(a)(1)(B) of the ESA.

1.1 Consultation History

USFWS Artificial Propagation Programs

On December 16, 1999, the USFWS requested initiation of formal section 7 consultation under the ESA concerning the potential effects of U.S. Department of Interior-funded artificial propagation of unlisted salmon on ESA-listed salmon and steelhead in the UCR basin. Included with the USFWS consultation request was a section 7 Biological Assessment (BA) addressing the effects of the Entiat, Leavenworth, and Winthrop National Fish Hatcheries (NFH) operations, including unlisted salmon releases, on listed Columbia River salmon and steelhead (USFWS 1999). The USFWS submitted proposed modifications to the BA on March 1, 2000, to provide further information regarding proposed actions and their effects on listed fish species through the federal hatchery operations evaluated in the BA (Cates 2000). The USFWS also provided additional information regarding water withdrawals associated with the proposed hatchery programs (USFWS 2000a), and a description of a new proposed hatchery program on the Okanogan River for NMFS review (USFWS 2000b). A May 2001 agreement between NMFS, USFWS, the Confederated Tribes and Bands of the Yakama Nation (Yakama Nation), the Confederated Tribes of the Colville Reservation (Colville Tribes), and WDFW further modified proposed USFWS unlisted salmon hatchery programs under review in this Opinion (WDFW 2001). The results of the 2001 agreement have been incorporated as proposed actions evaluated for effects on listed salmon and steelhead. Most recently, the USFWS submitted draft Hatchery and Genetic Management Plans (HGMPs) (USFWS 2002a,b,c) as an additional source of information for the programs being considered in this Opinion.

BPA Funded/Yakama Nation Operated Artificial Propagation Programs

NMFS had previously completed a section 7 consultation with the BPA/Yakama Nation on April 27, 1999 authorizing, for 1999 only, coho salmon releases in the region (NMFS 1999a). The 1999 NMFS Opinion required completion of a long-term management plan for restoration of coho salmon into the mid- and UCR basin. In response to that requirement, BPA/Yakama Nation submitted an HGMP to NMFS on December 13, 1999, describing the proposed coho salmon reintroduction program (BPA 1999). The HGMP includes plans proposed by the Mid-Columbia Coho Technical Work Group for coho salmon artificial propagation activities in

the region for 2000 and beyond (BPA 1999). In a subsequent letter to NMFS on March 17, 2000, the BPA noted that their submittal of the HGMP for the coho program comprised their formal request for initiation of consultation with NMFS on that program (Beraud 2000). In December 2002, NMFS received a revised HGMP from the BPA/Yakama Nation for the mid-Columbia Coho Reintroduction Project.

Public Utility District Funded/WDFW Operated Artificial Propagation Programs

In October 1999, NMFS received a request to operate artificial propagation programs, in the form of three HGMPs from the WDFW (WDFW 1999a, 1999b, 1999c). These HGMPs addressed programs in the UCR basin that artificially propagate and release unlisted summer chinook salmon, fall chinook salmon, and sockeye salmon. The summer chinook salmon and sockeye salmon programs are funded by the Chelan PUD and the Douglas PUD. The fall chinook salmon program is funded by the Public Utility District No. 2 of Grant County (Grant PUD), and the WDFW. The WDFW operates the hatchery facilities and is the lead co-manager of the anadromous fish resources in the state of Washington.

In April 2002, negotiations on three Habitat Conservation Plans (HCPs) were concluded; *Anadromous Fish Agreement and Habitat Conservation Plan Wells Hydroelectric Project FERC[1] License No. 2149* with Douglas PUD for the operation of Wells Dam (DPUD 2002), and *Anadromous Fish Agreement and Habitat Conservation Plan Rocky Reach Hydroelectric Project FERC License No. 2145* (CPUD 2002a) with Chelan PUD for the operation of Rocky Reach Dam, and *Anadromous Fish Agreement and Habitat Conservation Plan Rock Island Hydroelectric Project FERC License No. 943* with Chelan PUD for the operation of Rock Island Dam (CPUD 2002b). These HCPs are long term agreements between NMFS, the PUDs, the WDFW, the USFWS, the Colville Tribes, and other stakeholders. They provide the PUDs with some degree of certainty for the long-term operation of these projects and require the PUDs to provide mitigation in the form of a tributary fund for habitat improvement projects, and artificial propagation programs to mitigate for unavoidable loss of natural fish production due to habitat inundation and passage mortality at the projects. The HCPs were developed to protect five species of anadromous salmonids, including endangered UCR steelhead and UCR spring chinook salmon. The HCP agreements restrict the PUDs and NMFS from changing the artificial propagation production level during the period of this permit. The HCPs provide for HCP Hatchery Committees[2] that may adjust the operation or implementation strategy of the programs based on new scientific data, changes in NMFS hatchery policy, or recommendations of the HCP Hatchery Committees.

Many of the artificial propagation programs funded by the PUDs and operated by the WDFW are intended to supplement natural populations in the UCR basin by returning adult salmon to the spawning grounds and allowing them to reproduce naturally. This supplementation strategy necessitates monitoring in the natural environment, and has lead to the inclusion of monitoring, evaluation, and research actions that previously have been considered in separated formal section 7 consultations and section 10 authorizations to be included in this consultation. Assessment of the impacts of artificial propagation programs in the natural environment is critical to increasing

---

[1] *Federal Energy Regulatory Commission*

[2] *Each HCP agreement specifies the formation of a Hatchery Committee which consists of one representative of each signatory entity to the specific HCP. In general the HCP Hatchery Committee representation is likely to be similar for all three HCPs.*

our understanding of these programs after juvenile fish releases, and our ability to manage these types of actions to not only minimize adverse impacts on listed species, but to utilize these programs to conserve existing unlisted native populations to prevent future listings from being necessary. Activities previously authorized by permit 1203 issued to the WDFW that will be included in this consultation include spawning ground surveys to conduct redd counts and collection biological data from salmon carcasses, snorkeling surveys, and juvenile salmon capture actions that are specifically directed toward monitoring the artificial propagation programs impacts on the natural environment.

No long-term agreement concerning the operation of the Grant PUD hydropower projects has been reached, nor has NMFS received a permit application from the Grant PUD. The WDFW, as the artificial propagation program operator of the Grant PUD-funded programs, has submitted an HGMP for this program.

Public comment on the section 10 permit application (in the form of HGMPs) and the proposed issuance of permit 1347 was opened on October 16, 2001 (66 FR 52567), specific to WDFW operation of artificial propagation programs. On June 25, 2002 (67 FR 42755), a public comment period was opened specific to the HCPs, including Chelan PUD and Douglas PUD's obligation for artificial propagation programs to mitigate for unavoidable fish losses that result from operation of Rock Island, Rocky Reach, and Wells Dams.

A National Environmental Policy Act (NEPA) process addressing the PUD proposed actions of funding these artificial propagation programs was conducted, including public comment periods, which includes the development of an Environmental Impact Statement (EIS) (NMFS 2003a). An Environmental Assessment (EA) and Finding of No Significant Impact (FONSI) (NMFS 2003b) specific to the WDFW operation of the artificial propagation programs was also conducted, including a 30 day public comment period which opened on October 16, 2001 (66 FR 52567).

In developing this Opinion, NMFS considered information presented in documents submitted by the agencies, both federal and non-federal, operating the artificial propagation programs, and the three HCP agreements. Other sources of information considered in this Opinion include: the Biological Opinion on 1995 to 1998 Hatchery Operations in the Columbia River Basin (NMFS 1995), information in the NMFS report, *Pacific Salmon and Artificial Propagation Under the Endangered Species Act* (Hard *et al*. 1992), the *Biological Opinion on Effects on Upper Columbia River Spring Chinook Salmon Supplementation Program and Associated Scientific Research and Monitoring Conducted by the Washington Department of Fish and Wildlife and the U.S. Fish and Wildlife Service* (NMFS 2002a), the Artificial Production Review Report (NPPC 1999); and information available from the scientific literature. Additional information was received from federal and non-federal agencies, as indicated below, and in the "Literature Cited" section of this Opinion.

1.2 Analysis Framework

Over the course of the last decade and hundreds of ESA section 7 consultations, NMFS developed the following approach for applying the ESA Section 7(a)(2) standards as defined by 50 CRF §402.02 when determining what effect a proposed action is likely to have on a given listed species. In conducting analyses of the actions under Section 7 of the ESA, NMFS uses the following steps:

1. Define the biological requirements and current status of each listed species and the relevance of the environmental baseline to the species' current status in the action area (Section 3).

2. Determine the effects of the proposed or continuing action on listed species and their habitat and evaluate any cumulative effects within the action area (Section 4).

3. Evaluate whether the effects of the proposed action, taken together with any cumulative effects and added to the environmental baseline, can be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of the affected species or is likely to destroy or adversely affect their designated critical habitat (Section 5).

2 PROPOSED ACTIONS

This consultation addresses artificial propagation programs that rear and release unlisted spring chinook salmon and coho salmon with a federal nexus, operated by the USFWS and the Yakama Nation. NMFS is also consulting on its proposed issuance of an incidental take permit 1347, pursuant to section 10(a)(1)(B) of the ESA, jointly to the Chelan PUD, the Douglas PUD, and the WDFW on the operation of seven non-federal artificial propagation programs.

Table 1. Federal hatchery programs considered in this Opinion.

Hatchery Facility	Agency	Program	Annual production level
Leavenworth NFH	USFWS	Carson stock spring chinook salmon	1,625,000
Entiat NFH	USFWS	Carson stock spring chinook salmon	400,000
Winthrop NFH	USFWS	Carson stock spring chinook salmon [a]	600,000
Winthrop NFH	USFWS	Okanogan basin spring chinook salmon reintroduction	50,000
various	BPA/YN	Wenatchee basin coho salmon reintroduction	1,000,000
various	BPA/YN	Methow basin coho salmon reintroduction	250,000

[a] *Carson stock is being phased out and replaced with Methow Composite stock.*

Table 2. Non-federal hatchery (Chelan PUD, Douglas PUD, and WDFW) programs considered in this Opinion.

Implementing Entity Program	Hatchery Facilities	Annual production level
Chelan PUD		
Eastbank Hatchery is the central facility for these programs		
Wenatchee sockeye salmon	Lake Wenatchee Net Pens	200,000
Wenatchee summer chinook	Dryden Pond	864,000
Methow summer chinook	Carlton Pond	400,000
Okanogan summer chinook	Similkameen Pond	576,000
Turtle Rock summer chinook	Turtle Rock Hatchery	1,800,000
Douglas PUD		
Wells summer chinook salmon	Wells Hatchery	804,000
Grant County PUD [a]		
fall chinook salmon	Priest Rapids Hatchery	6,700,000

[a] *This permit for this program is proposed to be issued only to WDFW. Grant PUD is not part of the permit application at this time.*

Comprehensive descriptions of all proposed activities evaluated in this Opinion were presented in the BAs and HGMPs submitted to NMFS by the federal and non-federal action agencies (USFWS 1999; 2000a; 2000b; 2002a; 2002b; 2002c; BPA 1999; CPUD 2002a; 2002b; DPUD 2002; WDFW 1999a; 1999b; 1999c; 1999d). Updates or changes in the hatchery facilities and programs, including goals, broodstock collection strategies, and release numbers, were also included, as provided by the respective action agencies in BAs and HGMPs. A total of 13 hatchery programs (six federal and seven non-federal) with releases of approximately 15.3 million salmon smolts are proposed for operation and considered in this Opinion (Tables 1 and 2).

An early product of HCP negotiations was the *Biological Assessment and Management Plan* (BAMP) (1998) developed by technical representatives from the co-managers[3] and signatory entities of the HCPs. The BAMP included review and recommendation for all artificial propagation programs in the UCR basin, HCP related and otherwise. Although the BAMP does not create legal obligations as a stand-alone document, it does provide guidance for program management and monitoring and evaluation of UCR artificial propagation programs. The HCPs define the commitment by the PUDs for implementation of hatchery propagation programs for steelhead, summer/fall chinook salmon, spring chinook salmon and sockeye salmon for the middle and upper Columbia River region. The proposed actions addressed in this Opinion are derived from the HCP agreements, the WDFW HGMPs, the USFWS permit application, and the Yakama Nation HGMP.

[3] *Anadromous fisheries resource co-managers in the UCR basin include the WDFW, the USFWS, NMFS, the Colville Tribes, and the Yakama Nation.*

2.1 U.S. Fish and Wildlife Service

The USFWS operates the Leavenworth NFH Complex in the UCR region constructed by the U.S. Bureau of Reclamation (BOR) to replace fish losses that resulted from construction of Grand Coulee Dam. These programs were authorized as part of the Grand Coulee Fish Maintenance Project (GCFMP) on April 3, 1937, and re-authorized by the Mitchell Act (52 Stat. 345) on May 11, 1938. The complex consists of three hatchery facilities, Leavenworth, Entiat, and Winthrop NFHs, with the following mission:

> "*To produce high quality spring chinook salmon and summer steelhead smolts commensurate with the production goals established by the Columbia River Fisheries Management Plan*" (USFWS 2002a)

Historically, these facilities have reared and released spring chinook salmon eggs transferred from the Carson NFH on the lower Columbia River. Carson-stock spring chinook salmon are not included in the ESA-listed UCR spring chinook salmon ESU. The USFWS has discontinued transferring eggs from Carson NFH in favor of utilizing hatchery-origin adult spring chinook salmon returning to each facility as the primary egg source.

Artificial propagation program activities proposed by the USFWS include the collection of unlisted spring chinook salmon for broodstock; holding and spawning of broodstock; incubation of resultant eggs; juvenile fish rearing; externally marking by removal of the adipose fin (fin-clipping); internal tagging with coded-wire tags (CWTs) and/or passive integrated transponder (PIT) tags; release of yearling spring chinook salmon smolts into UCR basin tributaries.

Standardized, routine activities related to the proposed hatchery facility operations include:

- Monitoring of total suspended solids, settleable solids, and influent and effluent water temperature, and compliance with a National Pollutant Discharge Elimination System (NPDES) Permit No. WA-000190-2 (EPA 1977) issued for the hatchery operation.
- Following fish disease control policies as outlined by the "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" (NWIFC and WDFW 1998), the Integrated Hatchery Operation Team (IHOT 1995) and the Pacific Northwest Fish Health Protection Committee (PNFHPC 1989), to promote production of healthy fish and to reduce the incidence of diseases.
- Burying of spawned-out carcasses at these facilities to reduce the potential for fish disease transmission (USFWS 1999), or distribution in natural production areas for stream nutrient enrichment purposes, if appropriate disease-free certifications and permits are received.

Artificial propagation program and hatchery facility operational activities specific to the programs at each facility are detailed below.

2.1.1 Leavenworth National Fish Hatchery

The USFWS proposes to continue to operate the Leavenworth NFH to rear unlisted Carson stock spring chinook salmon. The annual fish production goal is 1,625,000 yearling spring chinook salmon smolts at a size of 15 to 18 fish per pound (fpp) which equates to approximately 137 to 146 mm fork length (fl) for release in April. External marking with an adipose fin-clip has

increased in the last few years from about 12 percent in 2000, to 18.5 percent (300,000 fish) in 2001, 34 percent (550,000 fish) in 2002, and 50 percent (810,000 fish) in 2003 (Cates 2000). A representative proportion of the total annual externally marked yearling release will also receive a CWT. In some years, PIT tags may be inserted into the smolt prior to release to monitor travel time, smolt migration survival, and smolt-to-adult survival. Increased hatchery fish marking will improve the ability to identify contributions to fisheries and escapement, and to monitor and evaluate straying of Carson stock spring chinook salmon adults to watersheds within the listed ESU, but outside of the hatchery release areas.

Returning adult spring chinook salmon are collected for broodstock as volunteers to the hatchery. The fish ladder and trap are typically operated from mid-May through July. The annual broodstock collection goal necessary to meet production levels for the hatchery is 1,000 adult fish.

An annual average of 1,282 spring chinook salmon adults trapped are surplus to broodstock collection. These surplus spring chinook salmon have been routinely distributed in unspawned condition to tribal and non-profit groups, including the Yakama Nation for ceremonial and subsistence purposes. Trout Unlimited, a private fish conservation organization, has also received surplus spring chinook salmon adults for various functions to raise money for fish restoration purposes (Dan Davies, USFWS, pers. comm.). About 350 surplus salmon have been released into Peshastin Creek for natural spawning in some years. The USFWS proposes to continue the above surplus spring chinook salmon distributions, including outplanting unspawned adults into Peshastin Creek.

2.1.2 Entiat National Fish Hatchery

The USFWS proposes to continue to rear and release unlisted Carson stock spring chinook salmon at the Entiat NFH with an annual production goal of 400,000 yearling spring chinook salmon smolts (13-18 fpp) for on-station release in April.

Adult spring chinook salmon are collected for broodstock as volunteers to the hatchery. The adult ladder and trap are typically operated to collect broodstock from mid-May through July. The annual broodstock collection goal for the facility is 350 adult spring chinook salmon. In addition, 100 adult fish from Entiat NFH will be made available for transfer to Omak Creek, in the Okanogan River basin, for spring chinook salmon reintroduction purposes (WDFW 2001). Although the intent is to meet broodstock collection and egg take goals for the program through spawning of fish recruiting to Entiat NFH, the USFWS proposes that egg take short-falls be augmented through transfers from Leavenworth NFH.

To improve monitoring and evaluation of Entiat NFH spring chinook salmon straying to natural production areas, other hatcheries, and other fish collection facilities in the region (e.g., Wells Dam), 100 percent of the Entiat NFH yearling spring chinook salmon production will be externally marked with an adipose fin-clip. A representative proportion of the total annual release of externally marked yearling fish will receive a CWT for fisheries contribution and fish survival evaluation purposes. The external marking, and the recovery of those fish receiving a CWT, will improve the ability to monitor and evaluate contribution to fisheries, and escapement to regional hatcheries, fish collection facilities, and natural spawning areas.

Distribution of adult Carson stock spring chinook salmon returning to the hatchery that are surplus to fish production needs to the Colville Tribes and Spokane Tribes will be maximized (WDFW 2001). Any remaining surplus fish will be used for local food banks, and for nutrient enhancement through carcass dispersion in the Entiat River watershed.

The USFWS has collected tissue sampled from spawning ground carcasses as a means to investigate the contribution and impact of the Carson-lineage artificial propagation program on the indigenous stock. They proposed to continue this sampling through at least 2005 return year.

2.1.3 Winthrop National Fish Hatchery

Winthrop NFH is one of two major anadromous salmon production facilities that operate in the Methow River basin. The hatchery is located adjacent to the Methow River in north-central Washington, near the town of Winthrop. The original hatchery purpose was to mitigate for the loss of salmon to fisheries due to lost habitat caused by the construction and operation of Grand Coulee Dam. Following the ESA listing of the local stock of spring chinook salmon in the Methow River basin, and the inability to maintain complete separation of the Carson stock fish from the listed stock, Winthrop NFH management objectives were modified to include the recovery of the local endangered stock. To achieve this new objective, the USFWS is in the process of discontinuing the Carson stock spring chinook salmon at this facility and transition to the Methow Composite stock. The annual production goal at Winthrop NFH is 600,000 yearling spring chinook salmon smolts (15-18 fpp) for on-station release in April. The USFWS released approximately 201,000 listed spring chinook salmon yearlings, and zero unlisted (Carson) stock yearlings from the hatchery in 2002, and 265,000 listed spring chinook salmon and 260,000 Carson crossed spring chinook salmon in 2003.

Spring chinook salmon adults can be trapped upon return as volunteers to the hatchery ladder. No weir is used to direct migrating spring chinook salmon adults in the Methow River into the hatchery. The Winthrop NFH fish ladder has typically been operated to collect spring chinook salmon adults from mid-May through July. The unlisted spring chinook salmon broodstock collection goal in 2000 was 357 adult fish. This collection goal was proposed to be reduced as the spring chinook salmon program is transitioned to the propagation of listed spring chinook salmon (USFWS 1999).

Under the 2001 Methow basin spring chinook salmon production agreement (WDFW 2001) and subsequent 2002 agreement (NMFS 2002b), no returning adult spring chinook salmon were collected at Winthrop NFH for use as broodstock. Spring chinook salmon gametes required to effectuate the program were collected at the WDFW's Methow Hatchery, or the Chewuch River trapping facility. All adult Carson stock fish returning to Winthrop NFH were prevented from entering the hatchery facility, and allowed to spawn naturally in the Methow River.

Unlisted Carson stock spring chinook salmon produced in previous years at Winthrop NFH have been, and will continue to be differentiated from listed spring chinook salmon at the time of spawning through on-site reading of CWTs removed from each fish.

Currently, Carson-lineage hatchery spring chinook salmon returning to the region from past juvenile fish releases cannot be differentiated from listed spring chinook salmon produced through the WDFW and USFWS supplementation programs by external examination. Both groups carry the same adipose fin-clip/CWT combination mark. Winthrop NFH-origin

Carson-lineage spring chinook salmon inadvertently collected with listed spring chinook salmon adults at Wells Dam or tributary trap sites have been transported to Winthrop NFH and the WDFW's Methow Hatchery for holding through spawning. Regardless of collection site, unlisted Carson spring chinook salmon and target, listed spring chinook salmon will be identified and separated during spawning at the hatcheries through on-site evaluation of CWTs removed from all fish. Carson-lineage spring chinook salmon adults identified through this process may either be used as broodstock for authorized unlisted salmon production programs, or left unspawned as surplus to production needs.

Under the 2001 and 2002 Methow agreements (WDFW 2001; NMFS 2002b), production of listed spring chinook salmon smolts is given priory over non-listed Carson stock smolts at Winthrop NFH. Future smolt releases will be confined to listed composite, native spring chinook salmon stock-origin fish beginning with the 2004 brood. As mentioned previously, unlisted Carson stock spring chinook salmon smolts, or Carson x listed spring chinook salmon crosses, will only be produced at the hatchery to prevent short-falls in the agreed, annual 1.15 million hatchery smolt production goal for the Methow basin through 2003 brood years (WDFW 2001, NMFS 2002b). Carson stock spring chinook salmon adults may be collected at Winthrop NFH to compensate for collection short-falls at the preferred WDFW listed spring chinook salmon trapping locations. Any smolts produced through Carson stock collections at the hatchery that are surplus to the number needed to meet Methow basin production needs would be outplanted into the lower mainstem Methow River or used for programs outside the Methow basin (NMFS 2002b). All listed spring chinook salmon smolts released from Winthrop NFH will receive an internal tag to allow for their identification at the time of spawning.

In 2000, a new program was proposed to reintroduce spring chinook salmon in the Okanogan River basin, using surplus Carson-lineage spring chinook salmon produced at Leavenworth Complex Hatcheries (including Winthrop NFH) as the primary brood-source (USFWS 2000b). This original proposal was modified through the 2001 "Methow/Upper Columbia Agreement" (WDFW 2001). The USFWS originally proposed to transfer 50 Carson-lineage marked adult spring chinook salmon pairs from Winthrop NFH to Omak Creek in the Okanogan River watershed for release each year, beginning in 2001 and extending through 2004. As a result of the 2001 Methow/Upper Columbia agreement, these adult fish will be made available from Entiat NFH (WDFW 2001). If water temperatures in Omak Creek are too high to allow successful transfer and survival of adult fish, USFWS proposes to plant 100,000 eyed eggs or marked fry that are progeny of Carson-lineage adults taken at Winthrop NFH as a substitute.

Beginning in 2001 and extending through 2005, the USFWS also proposed to produce and transfer 40,000 to 50,000 Carson-lineage spring chinook salmon yearlings to Omak Creek from Winthrop NFH. This yearling production is proposed to augment adult, egg, or fry out-plants. All yearling fish released into Omak Creek in 2001 were marked with a ventral fin-clip. Under the 2001 agreement (WDFW 2001), 300,000 Carson stock juveniles held at Winthrop NFH were raised to smolts, and out-planted in the Okanogan River basin. With the agreed, immediate phase-out of Carson stock production at Winthrop NFH, surplus spring chinook salmon yearlings for the Omak program will be provided in future years from either Entiat or Leavenworth NFH. Further details regarding the spring chinook salmon reintroduction program in Omak Creek are provided in the following section describing Okanogan River basin programs.

In addition to the Okanogan River spring chinook salmon reintroduction program, two other uses of surplus Carson stock spring chinook salmon have been proposed (USFWS 2000b). These

additional programs were originally proposed as "relief valve" measures to disperse excess Carson-lineage spring chinook salmon to appropriate release sites, as an alternative to culling surplus unlisted hatchery salmon. This option may be applied in future years to address Carson stock surpluses at regional hatcheries. The USFWS transferred up to 2.0 million unfed spring chinook salmon fry originating from surplus Carson-lineage spring chinook salmon adult returns to USFWS' Big White Salmon River NFH and WDFW's Ringold Hatchery for rearing and release (USFWS 2000b). USFWS indicates that as the phase-out of the Carson-lineage spring chinook salmon stock is completed at Winthrop NFH, these "relief valve" programs will be re-evaluated. The effects of juvenile spring chinook salmon releases and adult returns on listed salmonids resulting from the Big White River and Ringold programs are evaluated in a separate section 7 consultation pertaining to mid-Columbia River region hatcheries.

Through the 2000 release year, all spring chinook salmon yearlings released from Winthrop NFH into the Methow River have been marked with an adipose fin-clip/CWT combination for identification, and monitoring and evaluation purposes. Beginning in 2002, all spring chinook salmon smolts produced at the hatchery will be internally tagged (and if of Carson x Chewuch or other non-Carson origin, adipose fin-clipped) to allow for their differentiation from other listed and unlisted Methow basin fish upon return as adults to the region for spawning, hatchery fish survival evaluations, or stock assessment purposes. Annual monitoring by USFWS and WDFW includes recovery of straying hatchery fish in natural production areas and at other hatchery and fish collection facilities in the UCR region.

The proposed Okanogan River spring chinook salmon program is new. The reintroduction program in the basin began with releases of 1999 brood year fish in 2001, and will extend through 2005 (USFWS 2000b). The main purpose of the program is to release spring chinook salmon into a watershed that is believed by some parties to have historically supported this chinook salmon race. Original artificial production plans for the region (e.g. BAMP 1998) do not mention use of Carson stock spring chinook salmon for reintroduction purposes in the Okanogan basin. Past discussions have included use of the indigenous listed Methow "Composite" stock for this purpose, however very low adult return abundances and egg take levels have not yet allowed for any transfers of the stock out of the Methow basin. The parties to the 2001 "Methow/Upper Columbia Agreement" have indicated the need to identify the most appropriate stock for use in the Okanogan River basin (WDFW 2001).

As an outcome of the 2001 and 2002 agreements, the USFWS may transfer unlisted spring chinook salmon adults, eyed eggs, or fry, and pre-smolts or smolts from the Leavenworth Complex hatcheries (including 1999 and 2000 brood year juveniles from Winthrop NFH) for release into suitable habitat in Omak Creek, a left bank tributary to the Okanogan River near Omak, Washington. The source of unlisted spring chinook salmon to effectuate the introduction effort may include the other Leavenworth Complex hatcheries beginning with the 2001 brood year.

Facilities at Winthrop NFH used to support the Okanogan River spring chinook salmon reintroduction program were described above. The USFWS has recommended on-site acclimation of spring chinook salmon pre-smolts or smolts transferred to Omak Creek, to increase smolt to adult survival rates and to reduce potential straying of returning adult fish. The USFWS, WDFW, and Colville Tribes are currently identifying potential water sources and rearing locations for that purpose. Adult fish transferred by USFWS will be released directly into Omak Creek to spawn naturally. Eyed eggs, if produced for the program, will be incubated in

egg boxes at yet to be identified locations on Omak Creek to produce unfed fry. Spring chinook salmon fry transferred from Winthrop NFH or the other Leavenworth Complex hatcheries will be released directly into suitable habitat in Omak Creek.

The locations of the donor USFWS hatcheries and the Okanogan River are within the same Fish Health Management Zone (FHMZ). The FHMZs were defined by the Co-managers (WDFW and the Washington Treaty Tribes) as a means to limit disease transfer risks between isolated basins (NWIFC and WDFW 1998).

The proposed annual spring chinook salmon reintroduction goals for the program include release of 50 pairs of adult Carson-lineage spring chinook salmon into Omak Creek (USFWS 2000b; WDFW 2001). The adult spring chinook salmon release program would begin in 2001 and continue until August, 2004. The USFWS proposes to provide adult fish each year from Winthrop NFH, or if unavailable at Winthrop (as is likely with no broodstock collection in 2001 and phase out of production of the stock), from Entiat NFH or Leavenworth NFH. If release of unlisted adult spring chinook salmon is not feasible due to high water temperatures in Omak Creek (exceeding 55 degrees Fahrenheit) at the planned time of release, USFWS proposes to transfer up to 100,000 eyed eggs or 100,000 fry as a substitute. Beginning in 2003, Entiat NFH and Leavenworth NFH will be the donor sources, commensurate with phase out of Carson stock propagation at Winthrop NFH.

In addition to adult spring chinook salmon, or eyed egg or fry releases, USFWS proposes to transfer pre-smolt or yearling smolt spring chinook salmon to Omak Creek for acclimation prior to release. Transfers of pre-smolts and smolts began in spring 2001 and will continue through the 2005 release year. Approximately 40,000 brood year 1999 Carson-lineage yearling smolts were transferred from Winthrop NFH and released in 2001. Up to 50,000 yearling pre-smolts or smolts were proposed by USFWS for transfer and release in subsequent years (USFWS 2000b). Under the 2001 agreement (WDFW 2001), 300,000 brood year 2000 Carson stock juveniles initially reared at Winthrop NFH were transferred to an acclimation pond in the Okanogan basin for final rearing and were subsequently released in April 2002.

The USFWS proposes to externally marked with an adipose fin-clip all Carson-lineage spring chinook salmon adults released into Omak Creek through the program. An external mark will allow for differentiation of transferred hatchery fish from any natural-origin spring chinook salmon in Omak Creek. The progeny of naturally spawning hatchery spring chinook salmon transferred as adults to Omak Creek, and any eyed eggs transferred for incubation and release as fry, would not be marked. The USFWS recommended that eggressing fry or emigrating smolts that result from adult and eyed egg transfers be captured in Omak Creek and marked to evaluate their survival and to monitor straying of resultant adult fish.

All spring chinook salmon fry and yearling smolts transferred from the USFWS hatcheries to Omak Creek will also be externally marked. Marking of all fry stage or larger spring chinook salmon released into Omak Creek will allow for hatchery fish performance (e.g., juvenile to adult survival) and adult fish straying evaluations.

2.2 Bonneville Power Administration/Yakama Nation

The proposed long-term goal is to restore adult coho salmon populations in the UCR basins to their historical levels: 6,000 to 7,000 in the Wenatchee River basin, 23,000 to 31,000 in the Methow basin, and 9,000 to 13,000 in the Entiat basin (BPA 1999, historical levels from Mullan 1983). In identifying these production goals, Yakama Nation acknowledged that, due to varying degrees of habitat degradation in each of the basins, historical numbers used to establish the goals are unlikely ever to be achieved (BPA 1999; YN *et al*. 2002). The feasibility phase of the coho salmon restoration program is expected to extend from 2000 through at least 2005, perhaps longer for some studies. The Yakama Nation estimates an annual return (based on release numbers and assumed survival rates) of 2,100 to 3,800 coho salmon adults to the Wenatchee River, and 130 to 180 coho adults to the Methow River during the 2001 through 2005 period (Dunnigan *et al*. 2001). Following are descriptions of the coho salmon programs in the Wenatchee and Methow River basins. Specifics of a coho salmon program for the Entiat River have not been proposed at this time.

2.2.1 Wenatchee River Basin Coho Salmon Reintroduction

At this time, there is no central hatchery facility for coho salmon production in the UCR basin, and releases into the Wenatchee River basin rely on transfers from various facilities throughout the Lower and UCR basins of up to 1.0 million pre-smolts to existing rearing ponds (hatchery and natural locations) for acclimation prior to release (Table 3). Coho salmon broodstock for the Wenatchee Coho Reintroduction program will be collected in the Wenatchee River and spawned at a mid-Columbia facility, currently Entiat NFH. A broodstock collection goal of 1,400 coho adults is required for replacement in the hatchery environment (Murdoch and LaRue 2002). If necessary, to meet production goals, progeny from lower Columbia River hatchery broodstock for the BPA/Yakama Nation program will be incubated and reared at Willard NFH and/or ODFW's Cascade Hatchery in the Lower Columbia River. Pre-smolts (~20 fpp average size) produced at the lower Columbia hatcheries are transferred to Wenatchee basin acclimation sites in late winter or early spring the subsequent year. The broodstock collection phase of the lower river hatchery program will be described and analyzed in a separate NMFS section 7 consultation addressing Lower Columbia River basin unlisted salmon hatchery effects.

Adult coho salmon returning to the Wenatchee River basin are proposed to be collected at Dryden Dam and Tumwater Dam trapping sites, and possibly at Leavenworth NFH (ladder and "Dam 5"). The Winthrop NFH trap in the Methow River watershed will also be used to collect broodstock, whose progeny could be used to supplement releases in the Wenatchee River basin. The traps are proposed to be operational from September through early December at these locations, during which time coho salmon adults required as broodstock can be collected. Adult coho salmon returning to Leavenworth NFH will be trapped in the fish ladder, or at Dam 5 at the base of the old Icicle Creek channel. The Yakama Nation propose to operate the Dryden Dam trap passively 24 hours a day, 5 days a week to trap coho broodstock in the mainstem Wenatchee River. The Dryden trap would be checked by Yakama Nation staff once a day during this period. To provide an additional trapping option for the mainstem river, the Yakama Nation also propose to operate the Tumwater Dam trap to collect coho salmon broodstock or for monitoring and evaluation purposes. Under the proposal, the Tumwater trap will be operated 8 hours a day, three days a week, with the ladder open during the night, through December 8.

Table 3. Estimated source of proposed coho releases in the Wenatchee River basin.

Release year	Lower River [a]	Wenatchee production	Methow production	Total
1999	1,000,000	0	0	1,000,000
2000	1,000,000	0	0	1,000,000
2001	856,000	0	144,000	1,000,000
2002	400,000	600,000	0	1,000,000
2003	0	837,000	163,000	1,000,000
2004	0	1,000,000	0	1,000,000
2005	0	1,000,000	0	1,000,000

[a] *only if localized production is sufficient to meet total release numbers.*

In 2000, coho salmon adults captured at the Wenatchee basin trapping locations were held at the WDFW's Chiwawa Ponds through spawning. Eggs taken from the fish were incubated at Leavenworth NFH through the eyed stage, and transferred to Cascade and Willard hatcheries for hatching and for continued propagation. Broodstock holding, spawning, and incubation locations used to accommodate Wenatchee basin coho returns are subject to the availability of facilities. For 2002 and beyond, coho collected in the Wenatchee basin will be held and spawned at Entiat NFH; incubated to the eyed egg stage at Entiat NFH and transferred to Cascade and Willard NFH for final incubation and rearing. Coho salmon that return to their release site in the Methow River basin (Winthrop NFH) are held, spawned, incubated, and reared there (YN *et al*. 2002). Coho salmon adults spawned through the proposed programs will be buried or returned to the river.

In the Wenatchee River basin, the Yakama Nation propose to acclimate, rear, and release up to 1,000,000 coho salmon at several acclimation locations (Table 4). Sites have changed in the past due to research needs and/or landowner decisions, and they could change again in the future. Planned or previously used acclimation sites currently include Nason Creek (Butcher Creek and Early Pond), Beaver Creek, Coulter Creek, Mahar Creek Pond, Whitepine Beaver Pond, Little Wenatchee River (Two Rivers), Comstock Creek, Bender Creek and Icicle Creek (Leavenworth NFH old river channel through 2003, and then in unused small Foster-Lucas ponds on the Leavenworth NFH grounds). The Leavenworth NFH (the old Icicle Creek channel) and Butcher Creek sites are in operation (beginning in 1999). The Beaver Creek and Early Pond sites were used for coho smolt acclimation and release beginning in 2002. Additional sites, primarily in the Nason Creek watershed, are proposed for use beginning in 2003. Some have been and others will be subjected to an environmental analysis by the Yakama Nation.

Progeny from returning adults to the Wenatchee and Methow River basins will be planted into natural habitat areas as a first priority. If the number of progeny from returning adults (mid-Columbia brood) is low, then Lower Columbia River hatchery transfers will be released in natural habitat areas. Coho salmon pre-smolts will be transferred in February, March or April from Lower Columbia River hatcheries to the Wenatchee basin acclimation sites. The duration of acclimation generally ranges from four to six weeks post-transfer, after which time the fish are volitionally released. The target size range for coho smolts at the time of release is 110 to 120

mm fl (20 to 25 fpp), but because fish come from several hatcheries, a number of factors limit the Yakama Nation's control over final size. The expected volitional release period is April 15 through May 30 (YN *et al*. 2002.).

Permanent hatchery rearing locations required in the UCR region for progeny of adult coho salmon returns will not be proposed until feasibility has been demonstrated, although options have been identified. These include sites on the Chiwawa River, White River, Two Rivers (Little Wenatchee), Leavenworth NFH, Entiat NFH, and Dryden Dam, but others could be identified in the future (YN *et al*. 2002).

All phases of the coho salmon program will follow fish disease control policies outlined by the IHOT (1995) and the PNFHPC (1989) to reduce the incidence of diseases (YN *et al*. 2002). Fish will be monitored to detect and diagnose disease outbreaks at all production facilities.

Of the total annual number of coho salmon smolts transferred from Lower Columbia River hatcheries for release into the Wenatchee River, the BPA/Yakama Nation propose to mark 8,000 each year through 2002 with a PIT-tag for identification and monitoring and evaluation purposes. Of the total annual number of coho salmon smolts originating from adult collections in the Wenatchee River for release into the Wenatchee River basin, 17,000–24,000 (depending on funding) will be marked each year beginning in 2002 with a PIT-tag, to measure downstream smolt survival rates. All coho releases into the Wenatchee basin will be internally marked with a coded wire tag for evaluation. No external marking is proposed (YN *et al*. 2002).

Table 4. Estimated coho salmon smolt releases for the Wenatchee River basin for 2000 - 2005.

Release Year	Nason Creek	Beaver Creek	Two Rivers	Comstock Creek	Bender Creek	Leavenworth (Icicle Creek)	Total
2000	75,000					925,000	**1,000,000**
2001	75,000					925,000	**1,000,000**
2002	173,500 [a]	75,000		75,000		676,500	**1,000,000**
2003	306,000 [a]	75,000	100,800		37,500	453,100	**1,000,000**
2004	TBD	TBD	TBD	TBD	TBD	TBD	**1,000,000**
2005	TBD	TBD	TBD	TBD	TBD	TBD	**1,000,000**

[a] *Includes releases from Merritt Pond on Nason Creek.*
TBD: "To be determined". Release levels by site beyond 2003 to be determined through application of research results additional research needs, and to meet natural production goals.

The monitoring and evaluation program proposed for the coho salmon reintroduction effort is detailed in a HGMP submitted by the BPA/Yakama Nation (YN *et al*. 2002). Additional descriptions of research proposed to evaluate coho salmon smolt predation on spring chinook salmon fry, and coho salmon smolt interaction with sockeye salmon juveniles, were also submitted for review (YN 2001a; 2001b). Internal tagging of the juvenile coho salmon is proposed to estimate the smolt-to-adult survival rate for coho juveniles released into the Wenatchee River basin. A proportion of all coho salmon will be PIT-tagged to help identify the

proportion of smolt-to-adult mortality that is occurring in the freshwater migrant lifestage and to monitor year-to-year changes in juvenile fish survival.

Predation and species interaction studies are proposed for the Wenatchee River basin to determine the effects of the coho salmon release program on listed and unlisted salmon (YN 2001a; 2001b; YN *et al*. 2002). The BPA/Yakama Nation propose to operate a five-foot diameter rotary screw trap in Nason Creek at approximately rm 0.8 to capture emigrating coho salmon, and to evaluate coho smolt predation on spring chinook salmon juveniles (YN 2001a; YN *et al*. 2002). Subject to water conditions, the BPA/Yakama Nation may also use beach seines or electroshockers to collect coho smolts that may be holding upstream of the trap location. The trap will be located below the proposed coho release site on Nason Creek, and below all natural spring chinook salmon spawning areas in the creek. This trapping location therefore increases the likelihood for capture of emigrating hatchery and natural-origin salmon, and detection of predation, if it is occurring. The trap will be operated from mid-March through mid-June to encompass the expected emigration period for coho salmon smolts released from Nason Creek acclimation sites, as well as for a study of predation by "naturalized" smolts. The trap will be operated up to 12 hours per night, with staff checking the trap every hour during the hatchery predation study. During the study of predation by "naturalized" smolts, the trap will run 24 hours/day, seven days/week, and be checked as necessary (once to twice per day) until sufficient numbers of migrants warrant the start of stomach sample collection and hourly checks. The rotary cone will be locked in the "up" position when the trap is not in operation, for public safety purposes.

Fish captured (including coho collected by beach seine or electroshocker) will be anesthetized with MS-222 and enumerated by species. A random sample of the catch each day will be sampled to collect morphometric data. A total of 1,000 juvenile coho salmon will be randomly collected, sacrificed and preserved for later stomach content analysis. Stomach content data will be used to derive the incidence of spring chinook salmon fry predation, and then the estimated total number of chinook salmon consumed.

The BPA/Yakama Nation estimated that the operation of the Nason Creek trap may lead to the capture, handling, and release of up to 1,000 spring chinook salmon smolts and 500 fry each year, with an incidental lethal take of up to 20 smolts and 10 fry (YN *et al*. 2002). The BPA/Yakama Nation does not expect to encounter any listed adult spring chinook salmon because the timing of trap operation does not overlap with the June-July migration period or the August-September spawning period for adult fish (YN 2001a). Trap operation could also lead to capture, handling, and release of up to 500 steelhead juveniles, with an incidental lethal take of up to 10 smolts (YN *et al*. 2002).

The BPA/Yakama Nation also propose to continue a sockeye salmon/coho salmon interaction study in Lake Wenatchee which began in 2001 (YN 2002). The study has three components: coho radio-telemetry work designed to determine duration and route of hatchery coho emigration through Lake Wenatchee post-release; tow-net sampling and evaluation to determine the distribution of sockeye salmon fry in Lake Wenatchee during the coho smolt emigration period; and a study of coho smolt predation on sockeye, using an existing WDFW trap at the outlet of Lake Wenatchee. For the first component, the BPA/Yakama Nation proposes to radio-tag and release up to 150 coho migrating smolts (originating from Butcher Creek releases collected at the Nason Creek screw trap site) into the Little Wenatchee and White Rivers from 1-2.5 miles upstream of Lake Wenatchee. Radio-tagged smolts will be tracked in Lake Wenatchee and just

downstream of its outlet using a combination of six fixed monitoring stations and mobile tracking. Mobile tracking will occur by boat at four transects in the lake a minimum of 4 days per week, beginning the date of tagged fish release. Mobile tracking will continue along designated transects until the maximum tag life has passed, if not all coho have exited the lake (based on fixed station readings). The predation study would use methods similar to the Nason Creek predation study.

The proposed sockeye salmon fry distribution study will employ either a conical tow net or bongo-type tow nets (transect sampling) to collect fry. Seven sampling units have been identified for weekly fishing of the tow nets during April and May in 2002. Details regarding tow net sampling location, timing and tow duration are presented in Yakama Nation (2001b). The type of nets proposed for the study are designed to capture small fish without injury or mortality. The cod-end bucket proposed for use on the tow nets creates a safe reservoir for fish entrained in the net. Fish collected in the cod-end bucket will be removed after each ten-minute tow period, anesthetized with MS-222, and enumerated by species. A sub-sample of up to 20 fry from each 10 minute sample period will be measured and weighed. All fry will be allowed to recover before release into the lake. The BPA/Yakama Nation proposes to use a mid-water trawl to collect sockeye fry, in the event that the bongo-type tow nets prove ineffective (YN 2001b). The mid-water trawl is constructed of 1' stretch mesh near the opening, decreasing to 1/8" mesh at the cod-end. The trawl has a 6' by 6' square opening and is 21 feet long. In the littoral zone the BPA/Yakama Nation proposes to snorkel or employ beach seines to locate sockeye fry.

The radio-telemetry portion of the species interaction study should not affect listed spring chinook salmon. During 2002, the Yakama Nation staff captured only sockeye salmon fry and sockeye salmon smolts. All smolts were released uninjured (no descaling or visible injury). No bull trout or spring chinook salmon were encountered in 2001 or 2002. If spring chinook salmon are present in the lake, they are not pelagic and will not be found in the center as sockeye salmon are (where we are tow netting). Spring chinook salmon would be found only near the lake edges. Therefore, we estimate no take of spring chinook salmon or bull trout from tow netting.

In 2003, the project will begin a study of coho salmon predation on sockeye, using methods similar to those described for the Nason Creek predation study. The Yakama Nation would collect coho smolts using the existing WDFW trap at the outlet of Lake Wenatchee, beginning approximately March 1 and ending approximately June 30 (BPA 2001). The trap is normally operated 24 hours/day, 7 days/week.

In addition to the Nason Creek and Lake Wenatchee studies, the BPA/Yakama Nation propose to conduct foot and boat surveys in several Wenatchee basin tributaries where coho salmon smolts are released. These surveys will be used to determine where and how many adult coho return to spawn in areas where the fish were released. Genetic and morphometric data will be collected from returning adult coho salmon to monitor and guide reintroduction strategies, with the goal of determining production methods that will best lead to self-sustaining coho production.

The BPA/Yakama Nation proposes to evaluate the potential for naturally produced coho salmon to negatively impact steelhead and spring chinook salmon through competition of space and food during 2002 and 2003 (YN 2001a). They propose to release up to 33,000 hatchery coho fry as surrogates for naturally produced juveniles into Nason Creek between river kilometer 13.3 and the confluence with the Wenatchee River. Prior to fry releases, baseline distribution and habitat use by spring chinook salmon and steelhead will be determined by snorkel surveys. Juvenile

spring chinook salmon and steelhead will be collected using electroshocking to collect baseline size data. Post coho salmon fry release evaluation will include snorkel surveys and electroshocking to compare distribution, habitat utilization and size. In the spring of 2003, the Yakama Nation proposes to compare the predation rates of naturalized coho smolts that result from the fry releases to predation rates of hatchery reared and newly released coho smolts using their rotary screw trap located at RM 1.3 on Nason Creek. For this study the rotary trap will operate from mid-March through mid-June, and may be operated up to 24 hours per day. Coho released for this study are in addition to the 1,000,000 smolt releases described above.

Detection of PIT tagged emigrating juvenile coho salmon in mainstem Columbia River areas will help identify survival rates during emigration. Additional PIT tag and adult coho salmon abundance monitoring is mentioned as possible at Priest Rapids and Rock Island Dams, at Dryden and Tumwater Dams on the Wenatchee River, and at the WDFW's Chiwawa River weir (BPA 1999). A radio-telemetry study and extension of trap operations at Priest Rapids Dam and trapping for the radio-telemetry study at Tumwater Dam are also proposed (YN *et al*. 2002). Additional ecological interaction work being done for other projects in the Yakima River basin could benefit scientific understanding of the likely ecological effects of coho salmon production in the UCR region (BPA 1999). The results of the Yakima River studies may be used to indicate the potential for adverse effects on indigenous fish in the Wenatchee River basin resulting from the coho salmon reintroduction program.

Monitoring and evaluation plans may be discontinued, continued, or otherwise changed pending study results, and will be coordinated through the mid-Columbia Coho Technical Work Group.

2.2.2 Methow River Basin Coho Salmon Reintroduction

The Mid-Columbia Coho Reintroduction Program has both short- and long-terms goals for reestablishing coho salmon in the Methow River basin. Goal statements for the coho salmon reintroduction program are included in the above section describing the BPA/Yakama Nation coho reintroduction program in the Wenatchee basin.

Coho salmon broodstock proposed as the source for the Methow basin releases are spawned, incubated and reared at Winthrop NFH. If progeny of mid-Columbia returns raised at Winthrop are not sufficient to meet production goals, their numbers would be supplemented by eyed egg transfers from coho salmon eggs taken at Lower Columbia River facilities.

In the Methow River basin, the BPA/Yakama Nation propose to release acclimated coho salmon smolts from Winthrop NFH in a co-operative venture with USFWS. Hatchery progeny of Winthrop NFH adult coho salmon returns will be released as smolts in the Methow River watershed unless production from Wenatchee basin returns is insufficient to meet release goals in the Wenatchee.

All phases of the coho salmon program will follow fish disease control policies developed by IHOT (1995) and the PNFHPC (1989) to reduce the incidence of fish diseases. Fish will be monitored to detect and diagnose disease outbreaks at all production facilities.

Any adult coho salmon returning from Methow basin smolt releases are proposed to be collected at Winthrop NFH or Wells Dam. The Winthrop trap will be operational from September through November during which time coho salmon adults required as broodstock can be collected.

Experience in 2001 showed more returns (536) to the Methow River than the 100 – 125 projected in the 1999 HGMP. Even with the lower number projected in 2002 due to low juvenile survivals in 2000, the expected number is still approximately 200 (YN *et al*. 2002). As a result, numbers used for broodstock also could vary widely in future years (YN *et al*. 2002). The remainder of the adult coho salmon return to the Methow River basin is expected to spawn naturally, or be lost to pre-spawning mortality (YN *et al*. 2002).

The BPA/Yakama Nation also propose to collect coho salmon broodstock destined for the Methow River at the Wells Dam trapping locations if returns to the Methow are expected to be less than 150 coho salmon (YN *et al*. 2002). Trapping at Wells Dam would be done during the permitted WDFW steelhead broodstock collection period (YN *et al*. 2002). The WDFW currently operates the west ladder trap at Wells Dam 3 days per week, 16 hours per day from early July through the last week of October to collect steelhead from the run at large as broodstock for the Methow and Okanogan steelhead supplementation programs (WDFW 2000). The Yakama Nation propose to extend the trapping period at Wells Dam through the third week of November.

The current annual production goal for the Methow River basin is 250,000 yearling coho salmon smolts, released from Winthrop NFH (BPA 1999). The 250,000 number has been used because of production limits at Winthrop NFH, but could be increased in the future, depending on project needs. Progeny from returning adults to the Methow River basin are acclimated and released in the Methow basin (YN *et al*. 2002). If, however, an insufficient number of coho are spawned from Wenatchee River basin returns for release into the Wenatchee basin, progeny from adults returning to the Methow River will be released into the Wenatchee River basin.

Beginning in 1999, Winthrop NFH began incubation and rearing of eggs and juveniles from adults returning to the mid-Columbia. They have the capacity to rear up to 250,000 smolts per brood year, with two brood years on station at a time. If the production goal of 250,000 smolts cannot be met with mid-Columbia fish, coho will be transferred to Winthrop NFH as eyed eggs in December or January from Lower Columbia River hatcheries. The fish will be released volitionally in April. Of the 250,000 coho salmon smolts originating from Lower Columbia River hatcheries and released into the Methow River, 8,000 will be marked every third year with a PIT-tag for identification and monitoring and evaluation purposes. All coho salmon releases in the Methow River are marked with a coded wire tag for evaluation purposes. Survival evaluation will be based on coded wire tags recovered in broodstock and from carcasses recovered during spawning ground surveys (YN *et al*. 2002).

Monitoring and evaluation proposed for the coho salmon reintroduction program is detailed in an HGMP submitted by the BPA/Yakama Nation and WDFW (YN *et al*. 2002). Monitoring and evaluation of the effects of the coho reintroduction program on listed salmon and steelhead is proposed to be accomplished primarily in the Wenatchee basin (YN 2000). Currently, studies of predation by hatchery coho on sensitive species are planned only for the Wenatchee River basin.

For Winthrop NFH coho releases, internal tagging is proposed to estimate the smolt-to-adult survival rate for coho juveniles released into the Methow River basin. A proportion of all coho will be PIT-tagged to help identify the proportion of smolt-to-adult mortality that is occurring in the freshwater migrant lifestage, and to monitor changes in juvenile survival.

Genetic and morphometric data will be collected from returning coho salmon adults to monitor and guide reintroduction strategies, with the goal of determining production methods that will best lead to self-sustaining coho production.

2.3 National Marine Fisheries Service

NMFS proposes to issue section 10(a)(1)(B) permit 1347 as a jointly held permit to the WDFW, the Chelan PUD, and the Douglas PUD pursuant to the permit application, three HMGPs, and the three HCPs, to authorize take of listed species incidental to the implementation of sockeye salmon, summer chinook salmon, and fall chinook salmon artificial propagation programs in the UCR region. The HCP agreements for Rock Island, Rocky Reach, and Wells Dams with the Chelan PUD and the Douglas PUD require the PUDs to implement the proposed artificial propagation programs. Implementation may apply to anything necessary to carry out the artificial propagation programs within the boundaries of the HCP agreements. The WDFW is generally the lead co-manager of the fisheries resources of the state of Washington and is also the operator of the hatchery facilities in which the proposed artificial propagation activities would occur. Below is a description of the proposed activities followed by the conditions that NMFS would include in the permit to ameliorate potential negative effects. Together, the proposed activities and the conditions, imposed by NMFS, constitute the proposed actions considered in issuing the permit.

2.3.1 Chelan PUD and Douglas PUD Activities

The Chelan PUD and the Douglas PUD (PUDs) propose to provide artificial propagation compensation for spring chinook salmon, summer/fall chinook salmon, sockeye salmon, and coho salmon with origins upstream of Rock Island Dam, and summer steelhead as provided by the HCPs (CPUD 2002a; 2002b; DPUD 2002). Artificial propagation programs, facilities, release goals, and implementing PUD are listed in Table 2. Additional details of the PUDs proposed actions and obligations are provided in the three HCP agreements.

The PUDs, or their designated agents (currently the WDFW), propose to operate the hatchery facilities according to the terms of Section 8 "Hatchery Compensation Plan" of the HCPs (CPUD 2002a; 2002b; DPUD 2002), the ESA Section 7 and 10 permit(s), and in consultation with the HCP Hatchery Committees. The total number of each species artificially propagated in the UCR basin is not expected to change unless agreed to by the HCP Coordinating Committees following survival studies or until program reviews occur in 2013, which is outside the duration of this Opinion which is ten years.

The three HCP agreements result in the formation of HCP Hatchery Committees consist of one representative of each HCP signatory entity. NMFS will be represented in the HCP Hatchery Committee forum to ensure activities proposed by the HCP Hatchery Committees are consistent with ESA recovery goals and do not operate to the detriment of protected species.

The HCP Hatchery Committees will develop five-year monitoring and evaluation plans for the hatchery programs and updating them every five years. The PUDs will fund the implementation of the monitoring and evaluation plans. The first monitoring and evaluation plans shall be completed by the HCP Hatchery Committees within one year of the issuance of the FERC order incorporating the HCPs into the PUDs' licenses. Existing monitoring and evaluation programs shall continue until replaced by the HCP Hatchery Committees. The monitoring plans may

include data collection and analysis of all life stages of the salmon within the hatchery environment as well as data collection activities outside the hatchery facilities such as spawning ground surveys, juvenile fish traps, adult traps, and monitoring sites. Program-specific monitoring activities necessary to evaluate the programs will be determined by the HCP Hatchery Committees.

The PUDs agree that over the duration of the HCPs, new information and technologies that are developed will be considered and utilized in the monitoring and evaluation of the hatchery programs, if appropriate. The PUDs shall implement monitoring and evaluation of the hatchery programs consistent with the HCPs, the general objectives and guidelines listed for each Plan Species in the BAMP (1998) and as determined by the HCP Hatchery Committees.

There will be species-specific recommendations pertaining to each hatchery program that will evaluate the overall effectiveness of that program in meeting the goals and objectives of each program. These species-specific recommendation will be developed by the HCP Hatchery Committees, and the PUDs will be responsible for funding the implementation of those recommendations.

2.3.2 Washington Department of Fish and Wildlife Activities

Proposed artificial propagation activities include the collection of broodstock, spawning, incubation, rearing, acclimation, release of juvenile fish, monitoring and evaluation, and research tasks both within and outside the hatchery environment to assess each programs effectiveness in meeting program specific goals and objectives. Described below are the activities common to all the artificial propagation programs followed by program specific activities and special conditions proposed to be included in the permit.

The WDFW proposes to incorporate the following measures into all of the artificial propagation program operation to minimize potential negative impacts on ESA-listed species:

- Conduct routine water monitoring to ensure that the levels of total suspended solids, settleable solids, and water temperature at each facility to remain compliant with National Pollutant Discharge Elimination System (NPDES) permits issued by Washington Department of Ecology;
- Follow fish disease control guidelines developed by IHOT (1995) and the PNFHPC (1989) to reduce the incidence of fish diseases;
- Operate all rearing facilities compliant with "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" standards (NWIFC and WDFW 1998);
- Conduct routine, generally monthly, fish growth monitoring during rearing at each facility;
- Dispose of juvenile and adult carcasses via the local solid waste management system, on-station burial, or distributing carcasses into the river system of origin for nutrient enhancement after appropriate fish health certification.

Monitoring and evaluation plans, and research projects will be developed by the HCP Hatchery Committees as described in Section 2.3.1 (Chelan and Douglas PUD Activities). Additional details of the monitoring and evaluation plan development time lines and responsibilities are

provided in the three HCP agreements. Tasks proposed for consideration at this time, which, in all likelihood, will be included in the plans developed by the HCP Hatchery Committees, include monitoring within the hatchery facilities and monitoring of artificially propagated salmon in the natural environment.

Within-Hatchery Environment Monitoring

Monitoring and evaluation activities will be conducted on all of the salmon life stages that occur within the hatchery facility environment. The HCP Hatchery Committees are expected to fine-tune the evaluation activities through time to improve the knowledge base and success of the artificial propagation programs. The following tasks would be anticipated under current or future monitoring plans:

Adult salmon

- Broodstock (and mortalities at trap locations) would be sampled for stock composition analysis including determination of sex, age, and stray rates.
- Biological sampling may include meristic, morphometric, tissue samples (for genetic stock identification or DNA (deoxyribonucleic acid) analysis), and scale sampling.
- Snouts of CWT salmon would be collected.
- Annual determination of average fecundity will be conducted for a representative sample of spawned females in each program using an electronic egg counter.

Juvenile salmon

- Growth rate and general health will be monitored monthly.
- Unfertilized egg-to-eyed egg, eyed egg-to-fry, and fry-to-smolt survival rates will be determined.
- Numbers, size, and health condition of all salmon juveniles will be determined prior to or at the time of any transfers among facilities, and prior to release.

Natural Environment Monitoring

Natural environment monitoring of juvenile artificially propagated salmon will be conducted using a variety of standard techniques such as angling, trapping, and snorkeling. In general, these population sampling techniques will be used to identify both external marks and tags and internal tags. Only the Lake Wenatchee sockeye salmon program has a developed monitoring plan for post release monitoring of the juveniles which will be discussed in the program specific section below.

Monitoring of adult salmon returning to the UCR basin from the proposed programs would vary depending on the goals and objectives specific to the programs however, the following information will be collected to some extent on all adult monitoring programs:

- Routine biological data, such as length, sex, scale samples and snouts for CWT extraction would be collected on all carcasses encountered at trap sites, spawning ground surveys, and in carcass surveys;
- Spawning and carcass surveys would be conducted on foot, from an airplane, or from a boat, depending on area;
- Spawning and carcass surveys would be coordinated by WDFW as the lead staff in determining monitoring protocols in coordination with PUD, Tribal, USFWS, and U.S. Forest Service personnel;

- Spawning and carcass surveys would be designed to target about 20 percent of the escapement in a given area is sampled to ensure biologically substantial data is obtained;
- Creel surveys would be conducted on all fisheries occurring in the UCR basin that target unlisted salmon originating from these artificial propagation programs.

All subyearling sockeye and yearling summer chinook salmon released in the UCR basin will be externally marked with an adipose fin-clipped, and internally tagged with a CWT for identification and program evaluation. Fall chinook salmon released from Priest Rapids Hatchery are marked at a lower rate as described below. Subyearling chinook salmon released in the UCR basin are currently marked at a rate less than 100 percent. Brief artificial propagation program descriptions are provided below; additional information is available in the permit application and HGMPs.

2.3.2.1 Eastbank Fish Hatchery

The hatchery began operation in 1989 to mitigate for smolt losses resulting from the operation of Rock Island Dam. The hatchery is used for holding adult broodstock, spawning, incubation and rearing of steelhead, and spring chinook, summer chinook, and sockeye salmon. The hatchery is operated with five satellite facilities, located on five different water bodies; Dryden Pond on the Wenatchee River, Chiwawa Pond on the Chiwawa River, Lake Wenatchee Net Pens on Lake Wenatchee, Carlton Pond on the Methow River, and Similkameen Pond on the Similkameen River.

Broodstock are not collected at Eastbank Hatchery. There are no on-station releases of fish at Eastbank Hatchery into the mainstem Columbia River. Production and transfer goals for Eastbank Hatchery are: 864,000 Wenatchee summer chinook salmon for acclimation and release into the Wenatchee River basin, primarily from Dryden Pond; 200,000 Wenatchee sockeye salmon for acclimation and release from net pens in Lake Wenatchee, Wenatchee River basin; 400,000 Methow/Okanogan summer chinook salmon for acclimation and release in the Methow River basin primarily from Carlton Pond; and 576,000 Methow/Okanogan summer chinook salmon for acclimation and release in the Okanogan River basin generally from the Similkameen Pond.

2.3.2.2 Wenatchee Sockeye Salmon

The annual production goal for the Lake Wenatchee sockeye salmon program is 200,000 yearlings. Broodstock collection occurs at Tumwater Dam and fish are transported to the Lake Wenatchee Net Pens, a four to six net-pen array located in the north end of Lake Wenatchee, for holding through spawning. Eggs and juvenile sockeye salmon are incubated and early reared at Eastbank Hatchery. Juvenile sockeye are transferred to the Lake Wenatchee Net Pens for rearing and release.

The WDFW proposes to develop annual broodstock collection goals and protocols prior to the arrival of the adults each year to allow for consideration of run size, run composition in terms of sex, age, and natural to hatchery components with the following sideboards (WDFW 1999c; 2000):

- Retain broodstock from the Wenatchee River run at large at Tumwater Dam from July 15 through early August;

- Actively operated three days a week for eight hours per day;
- The broodstock collection goal is approximately 260 adults;
- To maintain the genetic integrity of the artificially propagated population, limit the number of adipose fin-clipped adult sockeye salmon used for broodstock to 10 percent of the total collection;
- To reduce the risk of adverse genetic effects on the founding natural population, the total collection is limited to 10 percent of the total run (WDFW 1999c).

The fish are transferred as juveniles to the net pens in early April to early July depending on rearing strategy. After four to seven months of rearing, the sockeye are liberated between August and October from the net pens into Lake Wenatchee at an average size of 17 grams (110 mm fl). The hatchery sockeye fingerlings overwinter in the lake, and emigrate to the ocean the following spring as yearling smolts. All net pen origin sockeye are identifiable from natural sockeye salmon by an adipose fin-clip and CWT (WDFW 1999c).

In addition to the monitoring and evaluation described above, WDFW operates a smolt trap on the Wenatchee River to collect sockeye salmon juveniles emigrating from Lake Wenatchee. The smolt trap is currently authorized in a section 10 research permit 1203 issued to WDFW (Table 3) which expires on December 31, 2003. The collection of listed spring chinook salmon and steelhead is authorized through this permit (1203), and the trapping program will not be analyzed in this Opinion.

2.3.2.3 Wenatchee Summer Chinook Salmon

The Wenatchee summer chinook salmon program release goal is 864,000 yearling smolts. The Eastbank Hatchery is used for holding broodstock, spawning, incubation and early rearing. Pre-smolt summer chinook salmon produced at Eastbank Hatchery are transferred to Dryden Pond on the Wenatchee River for acclimation and release.

The WDFW proposes to determine annual broodstock collection goals and protocols prior to the arrival of the adults each year to allow for consideration of run size, run composition in terms of sex, age, and natural to hatchery components. Broodstock collection protocols are generally as follows (BAMP 1998, with reference to annual co-manager review and approval of broodstock protocols):

- Retain predominately unmarked natural origin salmon for broodstock;
- Retain salmon throughout the duration of the run;
- Retain no more than 25 percent of the broodstock from Tumwater Dam;
- About 492 adult summer chinook salmon would be collected for broodstock;
- Follow established protocols for operation of the inflatable bladder at Dryden Dam;
- Operate the Dryden Dam right and left bank traps passively seven days per week and 24 hours per day during the trapping periods, which was between July 5 and November 17 in 2000 (WDFW 2000);
- Check traps daily and remove all captured fish;
- Fish not retained for broodstock will be released into the Wenatchee River, upstream from the collection site, utilizing water-to-water transfers;
- Operate the trap at Tumwater Dam actively three days each week for 8 hours each day between mid July and November;

- Delay operation of the Tumwater trap to collect salmon and steelhead broodstock is delayed until July to allow any late-arriving spring chinook salmon to clear the area;
- Open the Tumwater Dam trap open at night for unimpeded passage of migrating Wenatchee River salmonid populations, including listed steelhead.

The WDFW proposes to assist the Yakama Nation in collecting coho broodstock for the restoration program at the Dryden Dam and Tumwater Dam traps through the above trapping schedules, pending availability of the Yakama Nation personnel and tanker trucks when the traps are worked, primarily after mid-September (WDFW 2000).

All summer chinook salmon yearlings released from Dryden Pond are marked with an adipose fin-clip/CWT combination for visual identification, and for monitoring and evaluation purposes.

2.3.2.4 Methow Summer Chinook Salmon

The annual summer chinook salmon production objective in the Methow River is 400,000 yearlings at an average size of 10 fpp. There is no centralized summer chinook salmon production facility located in the Methow River basin. Eastbank Hatchery is used for spawning, incubation and early rearing. Summer chinook salmon juveniles are transferred to Carlton Pond on the Methow River in February for acclimation and released in April and May. Carlton Pond is located adjacent to the Methow River at river mile 35 near Twisp, Washington.

Summer chinook salmon adults used for the Methow program are trapped at Wells Dam, and held through maturity at Eastbank Hatchery. Summer chinook salmon destined for release into the Methow River are incubated and reared to fingerling size at Eastbank Hatchery. Juvenile fish reared are transferred as fingerlings in the late winter or early spring to Carlton Pond for continued rearing to yearling smolt size, and a spring release.

The WDFW proposes to determine annual broodstock collection goals and protocols prior to the arrival of the adults each year to allow for consideration of run size, run composition in terms of sex, age, and natural to hatchery components. The recent annual broodstock collection goal at Wells Dam ladder traps for the Methow summer chinook salmon supplementation program was 492, in combination with Okanogan summer chinook salmon program broodstock collection. Broodstock collection protocols are generally as follows:

- Trap at Wells Dam three days per week and 16 hours per day;
- Open the ladders for free upstream fish passage at night;
- Retain summer chinook salmon in equal number of males and females;
- Identify to species and count all salmonids encountered during trapping activities;
- Release all non-target fish back into ladder upstream of the traps;
- Allow all fish subjected to anesthetic to fully recovery in continual flow water prior to release back into ladder.

2.3.2.5 Okanogan Summer Chinook Salmon

The WDFW annual summer chinook salmon production objective in the Okanogan River basin is 576,000 yearlings at an average size of 10 fpp. Adult summer chinook salmon broodstock for this program are captured as described above with Methow River-origin summer chinook salmon

at the Wells Dam ladder traps between July and August as described above for the Methow summer chinook salmon program.

2.3.2.6 Turtle Rock Summer Chinook Salmon

The annual hatchery production goals are 200,000 yearling summer chinook and 1,600,000 sub-yearling summer chinook salmon for release from Turtle Rock Hatchery or (for 100,000 yearlings for Chelan PUD dam passage survival studies) above Rocky Reach Dam. Summer chinook salmon broodstock are not collected at Turtle Rock Hatchery. Currently, broodstock for the program is provided through collection of summer chinook salmon volunteers to the Wells Hatchery trap. Summer chinook adults collected at Wells Hatchery are a mixture of hatchery and a few natural-origin fish.

All yearling summer chinook salmon released from Turtle Rock Hatchery are marked with an adipose-clip and CWT combination for visual identification and monitoring and evaluation purposes. Progress is being made toward marking all sub-yearlings. Currently 200,000 "accelerated" (target release size of 20 fpp) sub-yearlings are marked and 200,000 "normal" release size (40 fpp) sub-yearlings are marked as a survival index group. Summer chinook salmon juveniles destined for release from Turtle Rock are transferred to the island ponds in November for six months of acclimation (April release of yearlings), or in April-May for three months of acclimation (June-July release of sub-yearlings).

The long-term strategy for summer chinook salmon production in the region is to transfer production from mainstem facilities (particularly Turtle Rock) to acclimation sites on upper river tributaries (or near mainstem spawning habitat) (BAMP 1998). This action would presumably benefit local adaptation, smolt to adult survival rates, and natural productivity.

A monitoring and evaluation plan for Turtle Rock releases will be developed by the HCP Hatchery Committees as previously described. Current post-release survival and contribution rates for Turtle Rock releases is monitored through the regional CWT recovery and evaluation program implemented by WDFW, the Tribes, and other fisheries management agencies in the Columbia basin.

2.3.2.7 Wells Summer Chinook Salmon

The annual Wells Hatchery on-station release goals are 320,000 summer chinook salmon yearlings released in April at an average size of 10 fpp and 484,000 accelerated sub-yearlings released in June at an average size of 20 fpp. Summer chinook salmon yearlings and sub-yearlings produced at Wells Hatchery are reared entirely at the hatchery and released directly into the mainstem Columbia River.

The WDFW proposes to determine annual broodstock collection goals and protocols prior to the arrival of the adults each year to allow for consideration of run size, run composition in terms of sex, age and natural to hatchery components. Broodstock collection protocols are generally as follows:

- Retain summer chinook salmon that volunteer to the Wells Hatchery trap from about July 10 through August 31, or until the summer chinook salmon broodstock collection objective is met, which ever is earliest;

- Retain approximately equal numbers of male and female salmon;
- Adult broodstock collection objectives may vary, but is generally about 1,210 salmon, contingent on HCP Hatchery Committee recommendations for survival studies throughout the middle and upper Columbia River region.

2.3.2.8 Priest Rapids Fall Chinook Salmon

The annual production goal is 6,700,000 fall chinook sub-yearlings for release in June. Fingerlings are acclimated on river water for release as sub-yearling smolts on-station. Approximately 4 percent of the total annual release (approximately 268,000 fish) receive an adipose fin-clip/CWT combination to assess brood year fishery contribution and survival rates (WDFW 1999c).

Fall chinook salmon broodstock are collected from September through November at the Priest Rapids Hatchery trap. The trap is located at the head of a ½-mile long hatchery water discharge channel tributary to the mainstem river, downstream of Priest Rapids Dam. The hatchery trap is presently not a "run of the river operation", relying only on hatchery adult returns volunteering to the trap (WDFW 1999c). The number of natural-origin fall chinook trapped at the hatchery each year is unknown (J. Sneva, B. Foster, WDFW, pers. comm.), but is thought to be low due to the location of the trap high in the outlet channel, and the use of well water to supply the channel to attract hatchery-produced adult fish. Broodstock collection is proposed with the following sideboards:

- Retain salmon broodstock across the entire run to ensure that the run timing for the population is maintained;
- When stray salmon from a program outside the mid-Columbia exceeds 5 percent, then remove those stray salmon from hatchery broodstock;
- Operate the Priest Rapids Hatchery trap three days a week during the September through November;
- Collection goal is 6,102 adult salmon.

Adult fall chinook salmon have, in the past, been collected from the east ladder trap in Priest Rapids Dam, but these fish were usually surplus to the hatchery's on station production needs. Although fall chinook adults have not been collected from the east ladder trap since 1989, the WDFW has proposed to collect run at large UBR fall chinook broodstock at the east ladder trap from September through November in years when collections at Priest Rapids Hatchery are below desired levels. The weekly effort of trap operation within this period is dependent on the abundance of chinook salmon migrating through the ladder, and the number of adult fish required to augment broodstock collections at the Priest Rapids Hatchery trap. Natural and hatchery-origin URB chinook salmon, and stray fall-run chinook salmon from other Columbia River regions may be taken in the east ladder trap. Migrating listed UCR steelhead may also be trapped incidentally when the east ladder trap is operated.

Approximately four percent of the fall chinook salmon produced through the program are marked with an adipose fin-clip/CWT combination. In addition, the Pacific Salmon Treaty's Chinook Technical Committee (CTC) has mandated marking a survival index group of 200,000 natural-origin Hanford Reach chinook salmon juveniles annually. The natural fish marking project is a cooperative effort with the Yakama Nation.

2.3.3 Permit Conditions

The following conditions will be required to minimize and reduce te level of incidental take associated with the proposed artificial propagation programs:

Production Levels

The following conditions address the production levels limits of unlisted chinook and sockeye salmon.

1. The WDFW shall limit annual production of sockeye salmon for release into Lake Wenatchee to not exceed 200,000 yearling juveniles released in August through November. These juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release.

2. The WDFW shall limit annual production of Wenatchee summer chinook salmon for release into the Wenatchee River to not exceed 864,000 yearling juveniles released in April to May. These juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release.

3. The WDFW shall limit annual production of summer chinook salmon for release into the Methow River to not exceed 400,000 yearling juveniles released in April or May. These juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release.

4. The WDFW shall limit annual production of summer chinook salmon into the Similkameen River or Okanogan River to not exceed 576,000 yearling juveniles released in April or May. These juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release.

5. The WDFW shall limit annual production of summer chinook salmon for release into the Columbia River from Wells Hatchery to not exceed 320,000 yearling juveniles released in April and 484,000 sub-yearling juveniles released in June. These juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release.

6. The WDFW shall limit annual production of summer chinook salmon for release from Turtle Rock Hatchery into the mainstem Columbia River shall not exceed 200,000 yearling juveniles released in April and 1,600,000 sub-yearling juveniles in June. The yearling juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release. At least 200,000 of the sub-yearling juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release.

7. The WDFW shall limit annual production of fall chinook salmon for release into the Columbia River from Priest Rapids Hatchery to not exceed 6,700,000 sub-yearlings, released in June. At least a portion of the juveniles shall be externally marked with an adipose fin-clip and internally tagged prior to release.

8. In the event that circumstances, such as unanticipated, higher-than-expected fecundity, or high egg-to-fry survival rates, lead to the inadvertent possession of salmon substantially

in excess (>110 percent) of program production levels specified above, then surplus eggs or fish shall be culled from the population in a manner consistent with achieving program goals.

Program Management and Operating Conditions

The following conditions address program management, fish handling, hatchery facility operations and monitoring and evaluations activities.

1. The Chelan PUD and Douglas PUD shall fund the specific elements of the artificial propagation programs objectives developed by the HCP Hatchery Committee, which may include contributing to the rebuilding and recovery of naturally reproducing populations in their native habitats, while maintaining genetic and ecologic integrity, and supporting harvest.

2. The Permit Holders are responsible for the actions of any individual operating inder the authority of this permit. Such actions include capturing, handling, and releasing any ESA-listed species authorized to be incidentally taken by this permit.

3. The Permit Holders must ensure that all ESA-listed species are handled carefully. Should NMFS determine that a procedure provided for under this permit is no longer acceptable, the Permit Holders must immediately cease such activity until an acceptable substitute procedure is identified and approved by NMFS Salmon REcovery Division.

4. Measures shall be applied to ensure that artificially propagated chinook salmon juveniles released will be ready to actively migrate to the ocean. To meet this condition, fish must be released at a uniform size and state of smoltification that ensures that the fish will migrate seaward without delay after release. Variance from this smolts-only release requirement shall only be allowed in the event of an emergency, such as flooding, water loss to raceways, or vandalism, that necessitates early release of ESA-listed steelhead to prevent catastrophic mortality. Any emergency releases made by the action agencies shall be reported immediately to the NMFS Salmon Recovery Division.

5. The Permit Holders must allow any NMFS employee or representative to accompany field personnel while they conduct authorized activities.

6. The Permit Holders are responsible for obtaining all other federal, state, and local permits/authorizations needed for the proposed activities.

7. The Chelan PUD and Douglas PUD shall be responsive to new information and technologies that are developed, and approved by the HCP Hatchery Committees, which may be considered and utilized in the monitoring and evaluation of the artificial propagation programs, where appropriate.

8. The Chelan PUD and Douglas PUD shall fund artificial propagation program monitoring and evaluation consistent with the HCPs, the general objectives and guidelines listed for in the BAMP, this Opinion, and as determined by the HCP Hatchery Committees.

9. The WDFW shall operate and manage the artificial propagation programs including following impact minimization measures as proposed in the section 7 Biological Opinion on the issuance of this permit.

10. To the extent possible without imposing increased risk to listed species, the Permit Holders shall enumerate and identify marks and tags on all anadromous species encountered at adult and juvenile trapping sites. This information shall be included in either an annual brood program report or a monitoring and evaluation report submitted to NMFS.

11. In trapping operations directed at the collection of broodstock, the Permit Holders shall apply measures that minimize the risk of harm to listed salmon and steelhead. These measures include, but are not limited to: limitations on the duration (hourly, daily, weekly) of trapping in mainstem river areas to minimize capture and handling effects on listed fish; limits on trap holding duration of listed fish prior to release; application of procedures to allow safe holding, and careful handling and release of listed fish; and allowance for free passage of listed fish migrating through trapping sites in mainstem and tributary river locations when those sites are not being operated.

12. All traps that have the potential to incidentally capture listed UCR spring chinook salmon or UCR steelhead when they are operated must be checked and have all trapped fish removed at least daily.

13. If water temperature at adult trapping sites exceeds 21°C (69.8°F), the trap operation shall cease pending further consultation with NMFS to determine if continued trap operation poses substantial risk to ESA-listed species that may be incidentally encountered.

14. The Permit Holders shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during trapping. The Permit Holders shall carefully handle and immediately release upstream incidentally captured listed UCR spring chinook salmon and steelhead adults that are not intended for use as broodstock in concurrently operated and otherwise authorized listed stock recovery programs.

15. The Permit Holders shall limit operation of Wells Dam east and west ladder traps to no more than three days per week from July through November. If both traps are operated, they shall be operated concurrently, operating on the same three days each week. When operating, active trapping may occur up to 16 hours per day. The ladder shall be open to passage at night to allow passage for listed steelhead.

16. The Permit Holders may operated Dryden Dam right and left bank traps up to 7 days per week to collect summer chinook broodstock from July through August. Incidental take of UCR steelhead shall not exceed 11 steelhead. Steelhead capture and handling authorized under permit 1395 will not count toward this incidental take limit.

17. The Permit Holders shall limit operation of Tumwater Dam trap for the collection of sockeye salmon broodstock to no more that three days per week, beginning after the sockeye migration peak at Rock Island Dam, but no earlier that July 15.

18. The WDFW shall collect fall chinook salmon adults volunteering to the Priest Rapids Hatchery trap as the primary means for obtaining broodstock for the Priest Rapids Hatchery program.

19. The WDFW may collect fall chinook broodstock at Priest Rapids Dam ladder trap as a secondary broodstock collection site. The incidental take of UCR steelhead shall not exceed 10 steelhead. Steelhead encountered during otherwise authorized activities, such as UCR steelhead run monitoring, authorized under permit 1395 shall not count toward this take limit.

20. The Permit Holders shall ensure that water intakes into artificial propagation facilities be properly screened in compliance with 1995 NMFS screening criteria and as per the 1996 addendum to those criteria (NMFS 1996). As an alternative, they shall comply with transitional criteria set forth by NMFS in 1999 for juvenile fish screens constructed prior to the establishment of the 1995 criteria (NMFS 1996), to minimize risks to listed salmon and steelhead. The Permit Holders shall inspect and monitor the water intake screen structures at their hatchery facilities to determine if listed salmon and steelhead are being drawn into the facility; the results of this monitoring shall be included in annual reports.

21. The Permit Holders shall implement the "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" (NWIFC and WDFW 1998) and Pacific Northwest Fish Health Protection Committee (PNFHPC 1989) guidelines to minimize the risk of fish disease amplification and transfer, and to ensure that artificially propagated fish would be released in good health.

22. The Permit Holders shall conduct hatchery operations and monitor hatchery effluent in compliance with applicable National Pollutant Discharge Elimination System (NPDES) (EPA 1999) permit limitations.

23. Visual observation protocols must be used instead of intrusive sampling methods whenever possible. This is especially appropriate when merely ascertaining the presence of anadromous fish.

24. The WDFW shall monitor and report Priest Rapids Hatchery fall chinook salmon contribution to natural spawning in the Hanford Reach, and straying levels to other Columbia River Basin watersheds, including mainstem river reaches upstream of Wanapum Dam. Information regarding contribution to natural spawning and straying to natural areas will be included in the annual report for the program.

25. The Permit Holders must coordinate with other co-managers and researchers to ensure that no unnecessary duplication and/or adverse cumulative effects occur as a result of the Permit Holder's activities. This coordination shall include, but is not limited to, the HCP Hatchery Committees.

26. The Permit Holders may conduct spawning ground and carcass surveys to assess the distribution and impact of artificially propagated salmon on the natural-origin opulations.

Reports and Annual Authorization

NMFS contact for all reports: NMFS - Salmon Recovery Division
525 NE Oregon Street, Suite 510
Portland, Oregon 97232
Phone: (503) 230-5407
Fax: (503) 872-2737

1. The Permit Holders must notify NMFS as soon as possible, but no later than two days after, any authorized level of take is exceeded or if such an event is likely. The Permit Holders must submit a written report detailing why the authorized take level was exceed or is likely to be exceeded.

2. The Permit Holders shall update and provide to NMFS by December 15th of each year, the projected hatchery releases by age class and location for the coming year.

3. The Permit Holders shall provide annual reports that summarize numbers, pounds, dates, tag/mark information, locations of artificially propagated fish releases, and monitoring and evaluation activities that occur within the hatchery environment, and adult return numbers to the UCR basin for each program. The Permit Holders shall ensure collection and reporting of the coefficient of variation around the average (target) release size immediately prior to their liberation from the acclimation sites as an indicator of population size uniformity and smoltification status. Reports shall also include any preliminary analyses of scientific research data, any problems that may have arisen during conduct of the authorized activities, a statement as to whether or not the activities had any unforeseen effects, and steps that have been and will be taken to coordinate the research or monitoring with that of other researchers. Unless otherwise noted in the specific terms and conditions, the reports shall be submitted by January 31st, of the year following release (i.e., brood year 2002, release year 2003, report due January 2004) to NMFS.

4. The Permit Holders must provide plans for future projects and/or changes in sampling locations or enhancement/research protocols and obtain approval from NMFS prior to implementation of such changes.

5. Adult return information shall include the most recent annual estimates of the number and proportion of artificially propagated fish on the spawning grounds, and the number and location of artificially propagated adults that were recovered outside the release areas. Adult return information and results from monitoring and evaluation activities outside the hatchery environment should be included in the annual report or a separate report. If a separate report on monitoring and evaluation activities conducted outside the hatchery environment is prepared, it shall be submitted by August 31st, of the year following the monitoring and evaluation activities (i.e., surveys conducted in 2003, report due August 2004) to NMFS.

6. The Chelan PUD and Douglas PUD, in coordination with the HCP Hatchery Committees, shall develop five-year monitoring and evaluation plans for the hatchery programs that are updated every five years. The first monitoring and evaluation plans shall be completed within one year of the issuance of the FERC order incorporating the HCPs into the hydroproject operation licenses. Existing monitoring and evaluation programs shall continue until replaced by the HCP Hatchery Committees.

7. The Chelan PUD and Douglas PUD shall assume the lead, and work in coordination with the HCP Hatchery Committees, in developing the ten-year hatchery program reviews and directing the development of annual summary reports. The program reviews will determine if egg-to-fry and smolt-to adult survival rates, and other appropriate hatchery program goals and objectives of the HCPs and the ESA section 10 permits have been met or sufficient progress is being made towards their achievement. This review shall include a determination of whether artificially propagated production objectives are being achieved.

8. The WDFW shall develop annual broodstock collection and spawning protocols for the sockeye and chinook salmon artificial propagation programs. Protocols should be coordinated with the co-managers and HCP Hatchery Committees which must be submitted to NMFS by April 15th of the collection year.

9. The Permit Holders must report the take of any ESA-listed species not included in this permit or authorized under a separate ESA permit, when it is killed, injured, or collected during the course of enhancement/research activities. Notification should be made as soon as possible, but no later than two days after the unauthorized take. The Permit Holders must then submit a detailed written report of the non-permitted take. Pending review of these circumstances, NMFS may suspend enhancement/research activities.

Penalties and Sanctions

1. The persons actually doing the activity must have a copy of this permit while conducting the authorized activities.

2. The Permit Holders may not transfer or assign this permit to any other person as defined in Section 3(12) of the ESA. This permit ceases to be in effect if transferred or assigned to any other person without NMFS' authorization.

3. If a permit holder violates any permit term or condition, they will be subject to any and all penalties provided by the ESA.

4. The Permit Holders, in effectuating the take authorized by this Permit, are considered to have accepted the terms and conditions of this permit and must be prepared to comply with the provisions of this permit, the applicable regulations, and the ESA.

5. The Salmon Recovery Division, NMFS, may amend the provisions of this permit after reasonable notice to the Permit Holder.

6. 50 CFR Section 222.23(d)(8) allows NMFS to charge a reasonable fee to cover the costs of issuing permits under the ESA. The fee for this permit has been waived.

7. Any falsification of annual reports or records pertaining to this permit is a violation of this permit.

8. Under the terms of the regulations, a violation of any of the terms and conditions of this permit will subject the Permit Holders, and/or any individual who is operating under the authority of this permit, to penalties as provided for in the ESA.

2.4 Action Area

The action area is defined as "all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action" (50 CFR §402.02).

Direct effects of the action of the issuance of all three permits would occur within the UCR basin and includes areas primarily in Chelan, Douglas, and, Okanogan counties; more specifically, the Columbia River at and above Priest Rapids Dam, the Wenatchee River, Entiat River, Methow River, and Okanogan River basins and artificial propagation facilities along the mainstem Columbia River (Figure 1).

The effected area in the Wenatchee River basin includes the Chiwawa River, Nason Creek, Dryden and Tumwater Dams, and all tributaries accessible to anadromous salmon. The effected area in the Methow River basin includes the Methow River, Twisp River, Chewuch River, the Methow Hatchery, the Winthrop NFH, and various smaller tributaries that are accessible to salmon. The effected area in the Okanogan River basin includes the Okanogan River, Similkameen River, Omak Creek, and Salmon Creek, and other small tributaries that are accessible to salmon. The effected area in the Columbia River basin includes the Wells, Eastbank, Turtle Rock, and Priest Rapids hatcheries and ladder traps at Wells and Priest Rapids dams.

Critical habitat was designated for UCR steelhead and UCR spring chinook salmon in 2000 when NMFS published a final rule in the Federal Register (65 FR 7764). However, the critical habitat designation for these ESUs was vacated and remanded to NMFS for new rulemaking pursuant to a court order in May 2002. The designation of critical habitat for the UCR spring chinook salmon and UCR steelhead ESUs will trigger a reinitiation of ESA consultation.

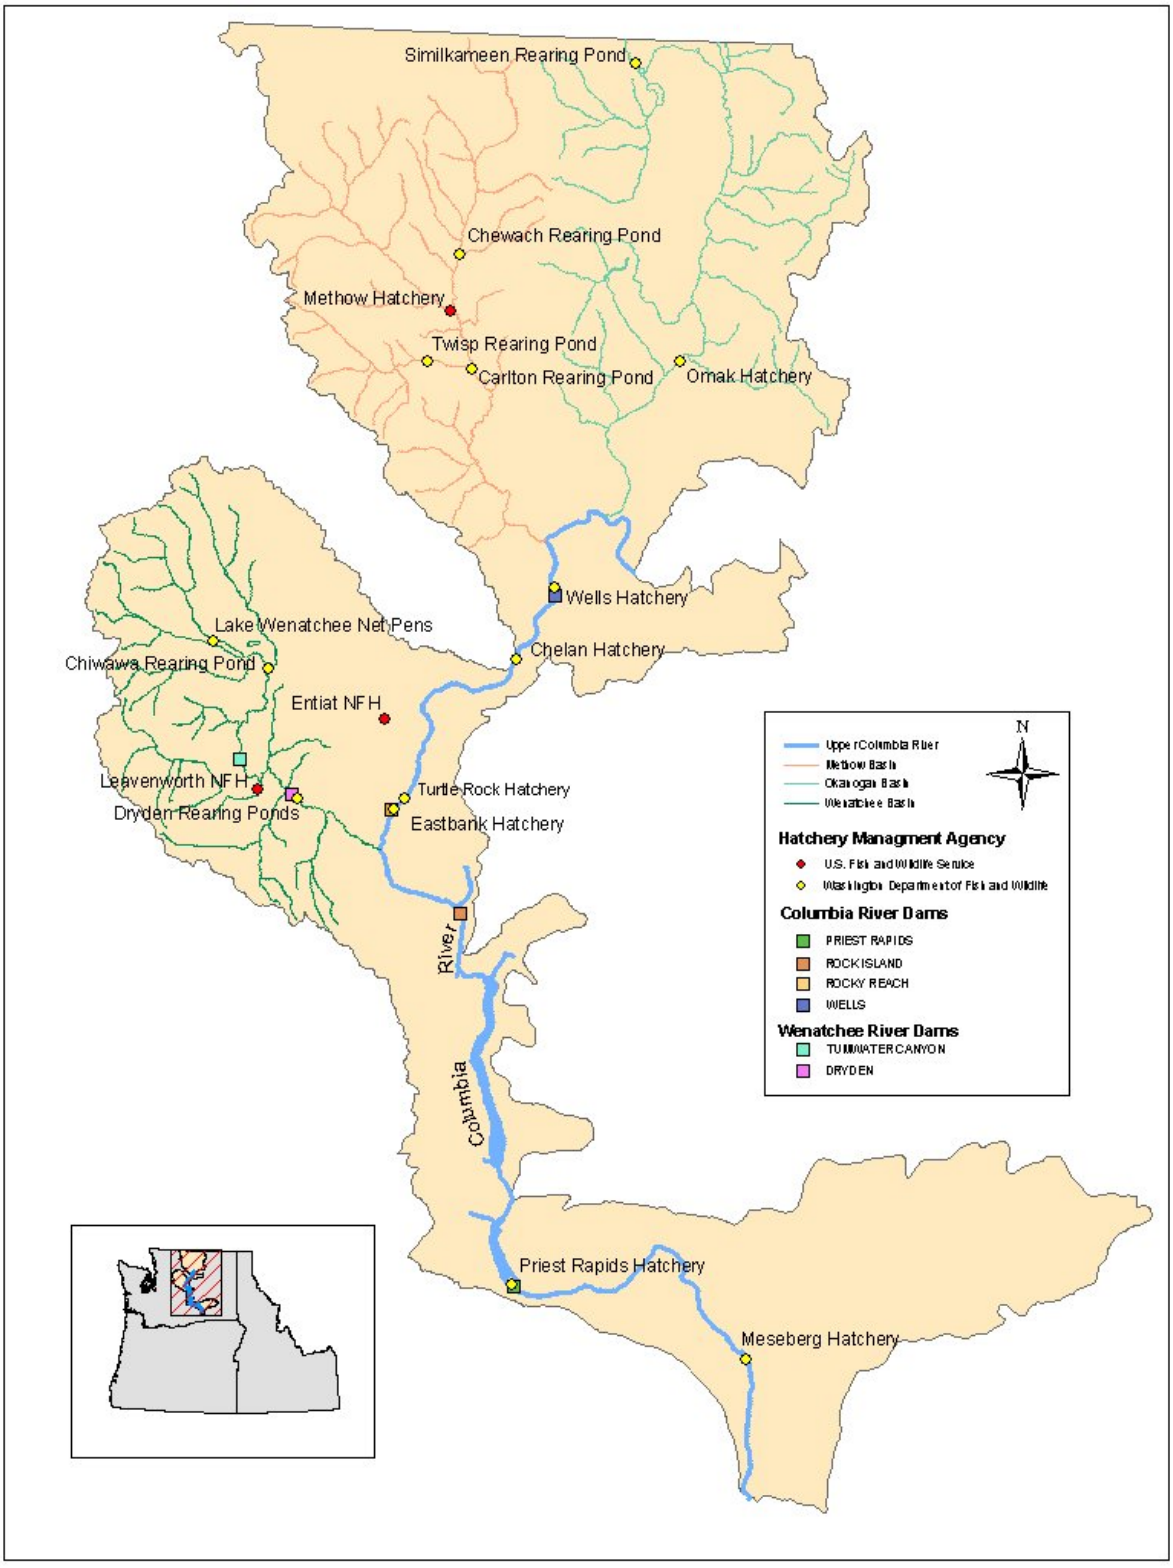

Figure 2. Map of the upper Columbia River basin with hatchery facilities and dams relevant to the proposed artificial propagation programs identified.

In order to describe a species' status, it is first necessary to define precisely what "species" means in this context. Traditionally, one thinks of the ESA listing process as pertaining to entire

taxonomic species of animals or plants. While this is generally true, the ESA also recognizes that there are times when the listing unit must necessarily be a subset of the species as a whole. In these instances, the ESA allows a "distinct population segment" (DPS) of a species to be listed as threatened or endangered. UCR steelhead and spring chinook salmon are just such DPSs and, as such, are for all intents and purposes considered "species" under the ESA.

NMFS developed the approach for defining salmonid DPSs in 1991 (Waples 1991). It states that a population or group of populations is considered distinct if they are "substantially reproductively isolated from conspecific populations," and if they are considered "an important component of the evolutionary legacy of the species." A distinct population or group populations is referred to as an evolutionarily significant unit (ESU) of the species. Hence, UCR steelhead constitute an ESU of the species *O. mykiss,* and UCR spring chinook salmon are an ESU of *O. tshawytscha*.

On March 24, 1999, NMFS listed UCR spring chinook salmon as an endangered species under the ESA (64 FR 14308). In its final listing determination, NMFS concluded that the UCR spring chinook salmon ESU is in danger of extinction throughout all or a significant portion of its range. NMFS also determined that six hatchery stocks in the UCR Basin (Chiwawa, Methow, Twisp, Chewuch, and White Rivers and Nason Creek) should be considered part of the ESU because they are currently essential for the recovery of the ESU. The WDFW operates most of the artificial propagation programs for listed UCR spring chinook salmon.

On August 18, 1997, NMFS listed UCR steelhead as an endangered species under the ESA (62 FR 43937). NMFS concluded that the UCR steelhead ESU is in danger of extinction throughout all or a significant portion of its range. NMFS also determined that one hatchery stock in the UCR basin, the Wells Hatchery stock, should be considered part of the ESU because it is currently essential for the recovery of the ESU. All artificial propagation programs rearing steelhead in the UCR were derived from the Wells Hatchery stock and natural origin UCR steelhead and are considered part of the ESU.

The UCR spring chinook salmon and steelhead were listed because NMFS determined that a number of factors—both environmental and demographic—had caused them to decline to the point where they were likely to become extinct within the foreseeable future. These factors for decline affect UCR chinook salmon and steelhead biological requirements at every life stage and they arise from a number of different sources. This section of the Opinion explores those effects and defines the context within which they take place.

To determine a species' status under extant conditions (usually termed "the environmental baseline"), it is necessary to ascertain the degree to which the species' biological requirements are being met at that time and in that action area. For the purposes of this consultation, UCR spring chinook salmon and steelhead biological requirements are expressed in two ways: Population parameters such as fish numbers, distribution, and trends throughout the action area; and the condition of various essential habitat features such as water quality, stream substrates, and food availability. Clearly, these two types of information are interrelated. That is, the condition of a given habitat has a large impact on the number of fish it can support. Nonetheless, it is useful to separate the species' biological requirements into these parameters because doing so provides a more complete picture of all the factors affecting UCR spring chinook salmon and UCR steelhead survival. Therefore, the discussion to follow will be divided into two parts: Species Distribution and Trends; and Factors Affecting the Environmental Baseline.

3.1 Species Distribution and Trends

3.1.1 Chinook Salmon

Chinook salmon are the largest of the Pacific salmon. The species' North American distribution historically ranged from the Ventura River in California to Point Hope, Alaska. In northeastern Asia, the species range from Hokkaido, Japan, to the Anadyr River in Russia (Healey 1991). Additionally, chinook salmon have been reported in the Mackenzie River area of northern Canada (McPhail and Lindsey 1970). Of the Pacific salmon, chinook salmon exhibit the most diverse and complex life-history strategies. Healey (1986) described 16 age categories for chinook salmon, seven total ages at maturity with three possible freshwater ages. Gilbert (1912) initially described two general freshwater life-history types: "stream-type" chinook salmon reside in fresh water for a year or more following emergence; "ocean-type" chinook salmon migrate to the ocean within their first year. Healey (1983, 1991) has promoted the use of broader definitions for "ocean-type" and "stream-type" to describe two distinct races of chinook salmon. This racial approach incorporates life history traits, geographic distribution, and genetic differentiation and provides a valuable frame of reference for comparisons of chinook salmon populations. The generalized life history of Pacific salmon includes freshwater phases of incubation, hatching, emergence, migration to the ocean, rearing in marine waters, and subsequent initiation of maturation and return to fresh water for completion of maturation and spawning. Juvenile rearing in fresh water can be minimal or extended. Additionally, some male chinook salmon mature in fresh water, thereby foregoing emigration to the ocean. The timing and duration of each of these stages is related to varying degrees of genetic and environmental determinants and interactions thereof. Chinook salmon may spend one to six years in the ocean before returning to their natal streams to spawn.

Ocean distribution differs between ocean- and stream-type chinook salmon (Healey 1983, 1991). Ocean-type chinook salmon tend to migrate along the coast, and stream-type chinook salmon migrate far from the coast in the central North Pacific. Chinook salmon populations can be characterized by their time of freshwater entry as spring, summer, or fall runs. Spring chinook salmon tend to enter freshwater and migrate far upriver, where they hold and become sexually mature before spawning in the late summer and early autumn. Fall chinook salmon enter freshwater in a more advanced stage of sexual maturity, move rapidly to their spawning areas on the mainstem or lower tributaries of their natal rivers and spawn within a few days or weeks of freshwater entry (Fulton 1968, Healey 1991). Summer chinook salmon are intermediate between spring and fall runs, spawning in large and medium-sized tributaries, and not showing the extensive delay in maturation exhibited by spring chinook salmon (Fulton 1968).

3.1.1.1 UCR Spring Chinook Salmon

The UCR spring chinook salmon ESU, listed as endangered on March 24, 1999 (64 FR 14308), includes all natural-origin stream-type chinook salmon from river reaches above Rock Island Dam and downstream of Chief Joseph Dam, including the Wenatchee, Entiat, and Methow River basins (Myers *et al.* 1998). All chinook salmon in the Okanogan River are apparently ocean-type and are considered part of the UCR summer/fall run ESU. Nine stocks have been identified within the UCR spring chinook salmon ESU (WDF *et al.* 1993). All stocks, with the exception of the Methow stock, were considered by WDF *et al.* (1993) to be of native origin, of natural production type, and as depressed in status. The WDFW considers the Methow spring chinook salmon stock to be a composite in production type, but of native origin, and depressed in status.

When listing the UCR spring chinook salmon as endangered NMFS included six hatchery populations as part of the ESU: Chewuch River, Methow River, Twisp River, Chiwawa River, White River and Nason Creek. These six hatchery populations were considered to be essential for recovery and were therefore listed as part of the ESU. Hatchery populations at Winthrop NFH, Entiat NFH, and Leavenworth NFH were not included as part of the ESU because they were derived from Carson NFH spring chinook salmon.

The UCR spring chinook salmon have a stream-type life history. Adults return to the Wenatchee River during late March through early May, and to the Entiat and Methow Rivers during late March through June. Most adults return after spending 2 years in the ocean, although 20 to 40 percent return after three years at sea. The UCR spring chinook salmon experience very little ocean harvest. Peak spawning for all three populations occurs from August to September. Smolts typically spend one year in freshwater before migrating downstream. There are slight genetic differences between this ESU and others containing stream-type fish, but more importantly, the ESU boundary was defined using ecological differences in spawning and rearing habitat (Myers *et al.* 1998). The Grand Coulee Fish Maintenance Project (1939 through 1943) may have had a major influence on this ESU because fish from multiple populations were mixed into one relatively homogenous group and redistributed into streams throughout the UCR region. A more detailed discussion of UCR spring chinook salmon is provided in the Biological Opinion concerning spring chinook salmon artificial propagation programs (NMFS 2000).

NMFS recently proposed Interim Recovery Abundance Levels and Cautionary Levels (Ford *et al*. 2001). *Cautionary Levels* were characterized as abundance levels that the population fell below only about 10 percent of the time during a historical period when it was considered to be relatively healthy. The three independent populations of spring chinook salmon identified for the ESU include those that spawn in the Wenatchee, Entiat, and Methow basins (Ford *et al.* 2001).

All three of the existing UCR spring chinook salmon populations have exhibited similar trends and patterns in abundance over the past 40 years. The 1998 status review (Myers *et al*. 1998) reported that long-term trends in abundance were generally negative, ranging from -5 to +1 percent. Analyses of the data series, updated to include 1996-2001 returns, indicate that those trends have continued. Based on redd count data series, spawning escapements for the Wenatchee, Entiat, and Methow rivers have declined an average of 5.6, 4.8, and 6.3 percent per year, respectively, since 1958. In the most recent five year geometric mean (1997-2001), spawning escapements were 273 for the Wenatchee population, 65 for the Entiat population, and 282 for the Methow population, only 8 to 15 percent of the interim abundance recovery targets, although escapement increased substantially in 2000 and 2001 in all three river systems. Based on 1980-2000 returns, the average annual growth rate for this ESU is estimated as 0.85. Assuming that population growth rates were to continue at 1980-2000 levels, UCR spring chinook salmon populations are projected to have very high probabilities of 90 percent decline within 50 years (87 to 100 percent).

Summary

While some improvement can be seen in recent years, the ESU is still at critically low levels compared to both historic production and the desired escapement levels—particularly for natural fish. Therefore, while there is some cause for very guarded optimism, there has been no genuine change in the species' status since they were listed as endangered, and the most likely scenario is that the biological requirements are not being met with respect to abundance, distribution, or overall trend.

3.1.2 Steelhead

Steelhead can be divided into two basic run types based on their level of sexual maturity at the time they enter fresh water and the duration of the spawning migration (Burgner *et al*. 1992). The stream-maturing type, or summer steelhead, enters fresh water in a sexually immature condition and requires several months in fresh water to mature and spawn. The ocean-maturing type, or winter steelhead, enters fresh water with well-developed gonads and spawns relatively shortly after river entry (Barnhart 1986). Variations in migration timing exist between populations. Some river basins have both summer and winter steelhead, others only have one run type. Unlike Pacific salmon, steelhead are iteroparous, or capable of spawning more than once before death. However, it is rare for steelhead to spawn more than twice before dying, and most that do so are females. Iteroparity is more common among southern steelhead populations than northern populations (Busby *et al.* 1996). Multiple spawnings for steelhead range from three percent to 20 percent of runs in Oregon coastal streams. Steelhead spawn in cool, clear streams with suitable gravel size, depth, and current velocity. Intermittent streams may also be used for spawning (Barnhart 1986, Everest 1973).

Based on catch data, juvenile steelhead tend to migrate directly offshore during their first summer, rather than migrating nearer to the coast as do salmon. During fall and winter, juveniles move southward and eastward (Hartt and Dell 1986). Available fin-mark and coded-wire tag data suggests that winter steelhead tend to migrate farther offshore but not as far north into the Gulf of Alaska as summer steelhead (Burgner *et al.* 1992). Maturing Columbia River steelhead are found off the coast of Northern British Columbia and west into the North Pacific Ocean (Busby *et al.* 1996). At the time adults are entering freshwater, tagging data indicate that immature Columbia River steelhead are out in the mid-North Pacific Ocean.

3.1.2.1 UCR Steelhead

The UCR steelhead ESU, listed as endangered on August 18, 1997 (62 FR 43937), includes all natural-origin populations of steelhead in the Columbia River basin upstream from the Yakima River, Washington, to the U.S./Canada border. The Wells Hatchery steelhead stock is considered essential for recovery, and is included in the listing.

The Wells hatchery stock is considered part of the UCR ESU because it was founded from a mixture of native populations and retains genetic resources of steelhead populations above Grand Coulee Dam that are now extinct. Since 1997, the WDFW has been developing a Wenatchee River stock for the juvenile released into the Wenatchee basin. Currently, there is probably a close resemblance between the natural and hatchery populations in this ESU because of the incorporation of naturally-spawning adults into the hatchery program and the large number of hatchery fish that have been spawning in the natural environment (65-80 percent of the spawning population in the Methow basin; Busby *et al.* 1996). Since natural replacement rates of UCR steelhead are low (0.3:1), the hatchery supplementation programs were determined to be essential for recovery and included in the endangered listing under the ESA. These hatchery fish could be used to reduce the short-term risk of extinction and aid in the recovery of the UCR steelhead ESU.

Although the life history of this ESU is similar to that of other inland steelhead, smolt ages are some of the oldest on the west coast (up to 7 years old), probably due to the ubiquitous cold water temperatures (Mullan *et al.* 1992). Adult steelhead from this ESU enter the lower Columbia between May and September with fish arriving at Wells Pool in early July. Fish enter the Wenatchee and Methow Rivers in mid-July and peak between mid-September and October.

During winter, adult steelhead generally return to the warmer Columbia River and re-enter the Methow to begin spawning in mid-March after the ice has thawed. Spawning continues through May and many fish seek out higher reaches in the tributaries. Fry emergence occurs that summer and juveniles rear for two to four years prior to spring downstream migration.

On April 4, 2002, NOAA Fisheries defined interim abundance recovery targets for each spawning population in this ESU (Lohn 2002). These targets are intended to represent the number and productivity of naturally produced spawners that may be needed for recovery, in the context of whatever take or mortality is occurring. They should not be considered in isolation, as they represent the numbers that, taken together, may be needed for the population to be self-sustaining in its natural ecosystem. For UCR steelhead, the interim recovery levels are 2,500 spawners in the Wenatchee River, 500 spawners in the Entiat River, and 2,500 spawners in the Methow River (Lohn 2002).

Returns of both hatchery and naturally produced steelhead to the UCR basin have increased in recent years. The average 1997-2001 return counted through the Priest Rapids Dam fish ladder was approximately 12,900 fish. The average for the previous five years (1992-1996) was 7,800 fish. Abundance estimates of returning naturally produced UCR steelhead have been based on extrapolations from mainstem dam counts and associated sampling information (e.g., hatchery/natural fraction, age composition). The natural component of the annual steelhead run over Priest Rapids Dam increased from an average of 1,040 (1992-1996), representing about 10 percent of the total adult count, to 2,200 (1997-2001), representing about 17 percent of the adult count during this period of time (BRT 2003).

In terms of natural production, recent population abundances for both the Wenatchee/Entiat river aggregate population and the Methow population remain well below the interim recovery levels developed for these populations (BRT 2003). A 5-year geometric mean (1997-2001) of approximately 900 naturally produced steelhead returned to the Wenatchee and Entiat rivers (combined) compared to a combined abundance target of 3,000 fish. Although this is well below the interim recovery target, it represents an improvement over the past (an increasing trend of 3.4 percent per year). However, the average percentage of natural fish for the recent 5-year period dropped from 35 to 29 percent, compared to the previous status review. For the Methow population, the 5-year geometric mean of natural returns over Wells Dam was 358. Although this is well below the interim recovery target, it represents an improvement over the past (an increasing trend of 5.9 percent per year). In addition, the estimated 2001 return (1,380 naturally produced spawners) was the highest single annual return in the 25-year data series. However, the average percentage of natural origin spawners dropped from 19 percent for the period prior to the 1998 status review to 9 percent for the 1997 to 2001 returns.

Naturally produced steelhead made up an average of 17.8 percent of the steelhead run at Priest Rapids Dam during the 18-year period from 1986 to 2001. These natural origin steelhead are not equally distributed among the UCR tributary basins. Mullen *et al*. (1992) reported annual escapement to the Methow basin at only 10 percent natural origin steelhead; however, in recent years the WDFW (2002) report natural origin steelhead composition of 12 to 29 percent in 1998 through 2000 at Wells Dam. The escapement to the Wenatchee basin from 1998 to 2000 averages 430 natural origin steelhead.

Summary

While some improvement can be seen in recent years, the ESU is still at critically low levels compared to both historic production and the desired escapement levels—particularly for natural fish. Therefore, while there is some cause for very guarded optimism, there has been no genuine

change in the species' status since they were listed as endangered, and based on the best available science, NMFS believes that the biological requirements are not being met with respect to abundance, distribution, or overall trend.

3.2 Factors Affecting the Environmental Baseline in the Action Area

Environmental baselines for biological opinions are defined by regulation at 50 CFR §402.02, which states that an environmental baseline is the physical result of all past and present state, Federal, and private activities in the action area along with the anticipated impacts of all proposed Federal projects in the action area (that have already undergone formal or early section 7 consultation). The environmental baseline for this biological opinion is therefore the result of the impacts a great many activities (summarized below) have had on UCR steelhead and spring chinook salmon survival and recovery. Put another way, the baseline is the culmination of the effects that multiple activities have had on the species' biological requirements and, by examining those individual effects, it is possible to derive the species' status in the action area.

The best scientific information presently available demonstrates that a multitude of factors, past and present, have contributed to the decline of west coast salmonids by adversely affecting these essential habitat features. These factors are well known and documented in dozens—if not hundreds—of scientific papers, policy documents, news articles, books, and other media. It is therefore unnecessary to detail in this opinion the many ways in which human activities and natural factors have affected the UCR steelhead's and chinook salmon's habitat-related biological requirements; thus the following paragraphs constitute a brief summary of what the most recent accepted science has to say about how human action and natural processes have degraded essential steelhead habitat features in the UCR subbasin.

Some factors in the action area (e.g., hydropower and agricultural development—particularly irrigation diversions) have had adverse effects on the habitat-related biological requirements of UCR spring chinook salmon and UCR steelhead, while other factors have only affected some of those essential habitat features. For example, road building in the UCR subbasin has had a sizeable effect on stream substrates and water quality (through siltation), and road culverts have blocked fish passage, but such activities have not had much of an effect on water velocity. In another instance, timber harvest and grazing activities have affected—to greater or lesser degrees—all the factors except space. And urban development has affected them all, but generally to a small degree in the largely rural UCR subbasin. In short, nearly every widespread human activity in the basin has adversely affected some or all of the habitat features. And by disrupting those habitat features, these activities—coupled with past hatchery and fishery effects and occasional natural disturbances such as drought and fire—have had detrimental impacts on UCR steelhead and spring chinook salmon health, physiology, numbers, and distribution in virtually every subpopulation and at every life stage. For detailed information on how various factors have degraded essential habitat features in the UCR subbasin, please see any of the following: NMFS (1991), NMFS (1997), NMFS (1998a), NMFS (2000), NMFS (2002), NMFS (2003) and, in particular, NMFS (2000b).

Summary

In conclusion, the picture of whether UCR steelhead and spring chinook salmon biological requirements are being met is more clear-cut for habitat-related parameters than it is for population factors: given all the factors for decline, it is clear that the UCR steelhead and spring chinook salmon biological requirements are currently not being met under the environmental baseline. Thus their status is such that there must be a substantial improvement in the environmental conditions of their habitat (over those currently available under the environmental

baseline). Any further degradation of the environmental conditions could have a large impact because the species is already at risk of going extinct. In addition, there must be efforts to minimize impacts caused by dams, harvest, hatchery operations, habitat degradation, and unfavorable natural conditions.

4 EFFECTS OF THE ACTIONS

NMFS analyzes the direct and indirect effects of an action on the species or its critical habitat, together with the effects of other activities that are interrelated or interdependent with that action that will be added to the environmental baseline. Indirect effects are those that are caused by the proposed action and are later in time, but still are reasonably certain to occur. Interrelated actions are those that are part of a larger action and depend on the larger action for the justification. Interdependent actions are those that have no independent utility apart from the action under consideration (50 CFR §402.02).

The proposed actions may result in incidental take of UCR spring chinook salmon and UCR steelhead. The applicants proposed protective measures and NMFS provides conditions that will be included in permit 1347 in order to minimize the extent of take. The following analysis is also considered in determining whether or not the artificial propagation programs pose substantial risk to the UCR spring chinook salmon ESU and UCR steelhead ESU.

4.1 General Effects

The *Biological Opinion on Artificial Propagation in the Columbia River* (NMFS 1999a), the *Biological Opinion on Effects on Upper Columbia River Spring Chinook Salmon Supplementation Program and Associated Scientific Research and Monitoring Conducted by the Washington Department of Fish and Wildlife and the U.S. Fish and Wildlife Service* (NMFS 2002a), and the *Biological Opinion on Artificial Propagation in the Hood Canal and Eastern Strait of Juan de Fuca Regions of Washington State* (NMFS 2002c) identify multiple general types of potential adverse effects of hatchery operations and production on natural fish populations. This analysis will consider the following general risks: (1) operation of hatchery facilities, (2) broodstock collection, (3) genetic introgression, (4) disease, (5) competition/density-dependent effects, (6) predation, (7) residualism, (8) nutrient cycling, (9) masking, (10) fisheries, and (11) monitoring and evaluation/research. A full discussion of each of these types of potential impacts is provided in the documents listed above. Furthermore, each of the biological opinions listed above conclude that artificial propagation programs that employ the basic hatchery reform measures or operate under the sideboards as defined in the Conditions (Section 2.3.3) for Permit 1347 are not likely to prevent the survival and recovery of listed salmon and steelhead in the ESUs affected by those programs. This Opinion considers the potential impacts of the specific artificial propagation programs as described in the Proposed Actions (Section 2) of this document in a manner consistent with the previously issued biological opinions listed above.

Adverse impacts cause by several of the general effect types listed above on UCR spring chinook and UCR steelhead by the proposed artificial propagation programs of unlisted salmon species are unlikely because of differences among the species. For example, none of the programs propose to rear steelhead therefore, no genetic introgression impacts are expected to occur on the UCR steelhead ESU, and no further analysis is provided in this Opinion. The proposed sockeye salmon and coho salmon programs are not expected to pose genetic introgression risks to UCR spring chinook salmon for the same reason, and are not further evaluated in this Opinion. However, the proposed summer chinook salmon and spring chinook salmon program pose some risk, which will be addressed in the specific effects on UCR spring chinook salmon section below.

Additionally some potential impacts are very general, such as operation of hatchery facilities, competition/density dependent effects, predation, disease, residualism, and monitoring and

evaluation effects and the means to minimize risk is largely the same for all of the programs. Those potential impacts and the methods to reduce impacts are summarized below. Programs that pose somewhat higher risks or whose specific impacts are quantifiable are further analyzed (Table 5).

Table 5. Categories of potential generic effects of artificial propagation programs and programs whose specific impact concerns are further analyzed.

Potential Effect Category	Programs with Specific Impacts of Concern
Operation of hatchery facilities	Leavenworth NFH
Broodstock collection	Leavenworth NFH; Entiat NFH; Coho Reintroduction Programs
Genetic introgression	Summer Chinook Programs; Leavenworth, Entiat, and Winthrop NFHs
Disease	None
Competition/density dependent effects	Entiat NFH; Coho Reintroduction Programs
Predation	Coho Reintroduction Programs
Residualism	None
Nutrient cycling	None
Masking	Leavenworth, Entiat, and Winthrop NFHs
Monitoring and evaluation	Coho Reintroduction Programs

4.1.1 Operation of Hatchery Facilities

Adverse impacts on listed fish due to the operation of hatchery facilities for the propagation of unlisted species may occur because of river water intake placement, or design, or operation including blocked migration, de-watering river reaches or reduced stream flow, and entrainment from unscreened or improperly screened intakes. Effluent from hatchery facilities may decrease quality through changes in water temperature, pH, suspended solids, ammonia, organic nitrogen, total phosphorus, and chemical oxygen demand in the receiving streams mixing zone (Kendra 1991).

Water withdrawal for use in hatcheries is monitored through the Washington State Department of Ecology and the Washington State chapter 90.03 Revised Code of Washington (RCW) water code. None of the hatchery facilities employed to carry out the proposed artificial propagation programs de-water river reaches used by listed fish for migration, spawning, or rearing.

In the Wenatchee River basin, all of the water intake systems at hatchery facilities that have surface water intakes are screened in compliance with NMFS screening criteria (NMFS 1996), except for the USFWS' Leavenworth NFH which is discussed in further detail in the specific effects on UCR steelhead section below.

The Lake Wenatchee Net Pens rely on passive flow, and do not withdraw water. Off-channel acclimation sites proposed for the coho salmon rearing are natural rearing locations, relying on spring flows. These sites are removed from listed fish rearing and migration areas and are screened to contain the hatchery fish for a limited rearing time. Modifications to those locations to accommodate fish rearing are minimal.

In the Entiat River basin, the Entiat NFH withdraws only a small portion of its water (up to 1,000 gpm) from the Entiat River during mid-February to mid-April and mid-May through July to supplement well water withdrawals. This is a period of relatively abundant water, and so the amount withdrawn is a small proportion of th stream flow. Juvenile fish screening associated with the Entiat NFH water intake is in compliance with NMFS screening criteria (NMFS 1996), and listed juvenile spring chinook salmon and listed steelhead are not expected to be adversely affected through entrainment.

In the Methow River basin, water intake sites are appropriately screened and in compliance with NMFS criteria and water withdrawals occur consistent with water rights granted by the state Department of Ecology. Withdrawal of 15 cfs of water from the Methow River for rearing summer chinook salmon at Carlton Pond occurs for only a short time during the year, from about late February to mid-April when the total stream flow is increasing because of spring run off.

Methow River water required for rearing spring chinook salmon and coho salmon at USFWS' Winthrop NFH is provided through a water intake at Foghorn Dam. In recent years, problems have arisen regarding the availability of sufficient river water for meeting salmon production needs at the hatchery using this water source. Head pressure and water volume available through Foghorn Dam have been reduced as a result of erosion of the dam structure, sedimentation of the bypass channel supplying water from the dam to the hatchery, and drought conditions in the region. The USFWS is currently working with the NMFS Habitat Conservation Division to develop measures to address water availability problems at the Foghorn Dam withdrawal point. The program is considered non-consumptive, returning water used for fish rearing to the river downstream of the point of withdrawal (Foghorn Dam). Any measures authorized by NMFS to increase flow volumes to Winthrop NFH will take into account instream flow needs for natural-origin, UCR spring chinook salmon in the Methow River reaches adjacent to the hatchery. NMFS expects that water withdrawal practices applied at the hatchery will continue to be protective of listed fish.

In the Okanogan River basin, the water diversion associated with Similkameen Pond is in compliance with NMFS screening criteria, and water is withdrawn consistent with a water right of 21 cfs held by WDFW and Douglas PUD. The water use is non-consumptive and only a small proportion of the average daily stream flow.

In the mainstem Columbia River, Eastbank Hatchery does not use any surface water, so no intake structures are associated with these operations, and no intake screening that may lead to listed juvenile fish injury through entrainment exists. Juvenile fish screening for the water intake systems at Wells Hatchery and Priest Rapids Hatchery are not in compliance with NMFS screening criteria (NMFS 1996). The facilities were built prior to the establishment of NMFS criteria. Douglas PUD is committed to be in compliance by November 2005 (Shane Bickford, pers. com., October 1, 2003). Routine intake screen inspections and upgrading to current screening criteria when existing screens fail are conditions which will be included in permit 1347. Without these conditions, water intakes for the hatchery may adversely affect listed spring chinook and steelhead juveniles through entrainment. Application of the conditions to the operation of these hatcheries through this Opinion will help ensure that the effects of the hatchery intakes on listed fish are adequately minimized.

The applicants propose to operated and monitor their programs in compliance with applicable NPDES permit effluent discharge limitations. Each permit contains limits concerning discharge, monitoring and reporting requirements, and other provisions to ensure that the discharge does not hurt water quality or people's health. In essence, the permit translates general requirements of

the Clean Water Act into specific provisions tailored to the specific hatchery facility operations and the discharge of pollutants. Although the actual level of impact of hatchery effluent discharge on listed fish survival is unknown, it is presumed to be small and localized at outfall areas, as effluent is diluted downstream. NMFS believes that programs operated in compliance with NPDES permits sufficiently minimize the likelihood for adverse effects on downstream aquatic life, including listed fish.

Based on the above discussion, compliance with NMFS screening criteria, adherence to Washington's water code and water rights, and all applicable NPDES permits, NMFS finds that the anticipated effects on listed species from operation of the hatchery facilities are minimal and are not likely to adversely impact listed species.

4.1.2 Broodstock Collection

Broodstock collection for the proposed programs would occur at various dams, traps and hatchery facilities, which include: Priest Rapids Hatchery and Wells Dam on the Columbia River, Dryden and Tumwater Dams on the Wenatchee River, Leavenworth NFH on Icicle Creek, Entiat NFH on the Entiat River, and Winthrop NFH on the Methow River.

Several of these sites are also used to collected UCR spring chinook salmon and UCR steelhead and are permitted to do so under separate ESA section 10 permits 1196, 1300, and 1395. Because of the targeted collection of the listed species under existing permits at the sites, incidental impacts on the listed stocks are minimal, but potentially could occur at Tumwater Dam, Leavenworth NFH, Entiat NFH, and Wells Dam and are further analyzed in the specific effects sections below.

At each broodstock collection location, all UCR spring chinook salmon and UCR steelhead encountered and not otherwise authorized for collection and retention would be released unharmed, upstream of the collection site. No substantial broodstock removal effects, including numerical reduction or selection effects, on listed UCR spring chinook salmon or UCR steelhead are likely to occur as a result of the proposed broodstock collection programs at Priest Rapids Hatchery, Dryden Dam, or Winthrop NFH.

Operation of unlisted summer chinook salmon and sockeye salmon broodstock collection programs at Dryden and Tumwater Dams is not likely to lead to the capture and handling of listed spring chinook salmon. The summer chinook salmon and sockeye salmon adults that are the targets of the trapping operations return to the Wenatchee River in July and August. It is unlikely that May-June migrating spring chinook salmon adults will be encountered in the trapping programs directed at these species. The WDFW delays operation of the Tumwater Dam trapping site until after July 15 as an additional measure to preclude takes of any late-arriving or delaying spring chinook salmon that may be present in Tumwater Canyon.

4.1.3 Genetic Introgression

As mentioned above, species differences between the unlisted chinook, sockeye, and coho salmon prevent genetic introgression to effect the UCR steelhead ESU. Additionally, species difference between the listed UCR spring chinook and the propagated coho and sockeye salmon are not possible. Potential effects of propagating chinook salmon are discussed below in the species specific effects section.

4.1.4 Disease

Risks of fish disease transmittal to listed natural fish may be posed by the proposed artificial propagation programs. Disease transmittal may occur while unlisted salmon are held in the hatchery facility through horizontal transmission of fish pathogens (if present) to listed species in the natural environment by exposure to hatchery effluent, or through contact with the hatchery fish after they are released.

The Columbia River watershed is a single "Fish Health Management Zone" under the "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" (NWIFC and WDFW 1998), and transfers of salmon within the same zone are allowed from a fish disease management perspective. Regulated pathogens include bacterial kidney disease (BKD), which occurs routinely at virtually all of the facilities that rear chinook salmon, and the pathogen is ubiquitous in Columbia River basin chinook salmon populations, and infectious hematopoietic necrosis virus (IHNV), which has also been identified in adult chinook salmon returning to hatchery facilities in the UCR basin. North American viral hemorrhagic septicemia virus (VHSV) is also regulated, as is *Myxobolus cerebralis* (the protozoan causing whirling disease) which has not been found in the UCR basin. The proposed artificial propagation program will be operated to comply with these guidelines.

In addition, fish health protocols will be followed in accordance with Pacific Northwest Fish Health Protection Committee (PNFHPC 1989) and Integrated Hatchery Operations Team (IHOT 1995) guidelines for all programs. To reduce the likelihood for the amplification of fish disease, the incidence of viral pathogens in all salmon broodstocks is determined by sampling fish at spawning in accordance with procedures set forth in the above documents. Fish health and condition would be monitored routinely during rearing by fish health professionals for each proposed program. Additionally, juvenile fish undergo fish health sampling prior to transfers between facilities and prior to release into the natural environment. NMFS finds that implementation of these guidelines is sufficient to minimize the risk of fish disease amplification through hatchery spawning practices, and disease transmission to listed adult fish outside of the hatcheries.

There is a risk that the intra-basin transfer of coho salmon for the BPA/Yakama Nation program may introduce coho anemia disease (CAD), a non-regulated pathogen, into the Wenatchee River and Methow River basins, as CAD has been detected in certain Lower Columbia River hatchery coho salmon stocks. However, there is no evidence at this time that CAD is vertically or horizontally transmitted to other stocks (BPA 1999), and fish health pathologists will continue to monitor coho salmon for signs of CAD and to identify the causative agent for this disease. In addition, VHSV was identified in 1999 brood coho salmon adults at WDFW Lewis River Hatchery, indicating that there is a risk of the transfer of this disease from coho salmon reared at the designated, donor federal and state hatcheries in the lower Columbia River. Lewis River Hatchery is currently not used as a source of coho salmon pre-smolts for the BPA/Yakama Nation program, and coho reared at the Willard and Eagle Creek NFHs, and Cascade Hatchery, are being monitored for this regulated pathogen. NMFS finds that the existing fish health protocols are sufficient to minimize the above risks.

The general policy of the WDFW, the USFWS, and the Yakama Nation is to bury juvenile fish mortalities, and dead eggs to minimize the risk of disease transmission to natural fish. The action agencies may place at least some of the adult salmon carcasses in regional streams for nutrient enrichment purposes, consistent with permitting and disease certification protocols. If adult carcasses are not used for nutrient enhancement they will be buried or disposed of at a local

waste disposal site. The distributing of spawned, dead carcasses into the natural environment should benefit natural fish productivity through nutrient enrichment. NMFS finds that risk to the listed populations is minimal if disease certification protocols are followed.

4.1.5 Competition/Density Dependent Effects

When artificially propagated salmon are released into the natural environment, the potential exists for intra- and interspecific competition with natural-origin juvenile salmonids, including listed UCR spring chinook salmon and UCR steelhead. Risks are likely to be greatest near the point where the hatchery fish are released, diminishing as the hatchery smolts disperse downstream. Artificially propagated salmon could cause displacement of rearing listed spring chinook salmon and steelhead from occupied stream areas, leading to abandonment of advantageous feeding areas or premature out-migration (Pearsons *et al.* 1994).

The release of migration-ready juveniles beginning the smolting process limits the duration of interaction between the artificially propagated fish and listed naturally produced fish rearing in areas adjacent to, and downstream of, the release locations. This release practice therefore likely decreases resource competition and behavioral dominance risks posed by the larger hatchery fish. The large size of the hatchery fish relative to the natural fry and fingerlings present at the time of the releases also decreases the likelihood for competition for the same food resources by the hatchery and natural fish. The larger, seaward-migrating hatchery smolts will also tend to use different habitat than rearing listed steelhead and spring chinook salmon fry and fingerlings that may be encountered.

Adult salmon and steelhead have evolved a variety of strategies to partition available resources among species that are indigenous to a particular watershed. Artificially propagated salmon may compete with different species of natural origin salmon and steelhead for redd sites, with the same species of salmon for mates and redd sites, or stray into areas other than the release site. In general, the proposed programs use local, native stocks of salmon in the artificial propagation program. Juvenile fish are released into areas where adult returns are desired to supplement the natural origin spawners as a specific goal of the program. The non-native stock of spring chinook salmon propagated at Leavenworth, Entiat, and Winthrop NFHs and the non-native coho salmon pose higher competitive risks upon return to listed species which are discussed in detail in the specific effects sections below.

4.1.6 Predation

Risk of predation on listed UCR spring chinook salmon and UCR steelhead juveniles by artificially propagated is minimized through several general mechanisms. The proposed artificial propagation programs release migration ready juveniles at the appropriate time for migration based on natural origin salmonid migration and coincident with spill at Columbia River dams. The only exemption to this is the Wenatchee sockeye salmon program which released juvenile sockeye into Lake Wenatchee in the late summer or fall for over-winter rearing in the lake. At release, the average length of sockeye release groups ranges from about 73 - 122 ml. Sockeye salmon are not recognized as piscivorous, therefore predation on listed salmon and steelhead is not likely.

Coho salmon yearlings have the potential to prey upon listed fish in the action area. In its analysis of the effects of the proposed coho salmon reintroduction program on indigenous fish in the Wenatchee River basin, BPA (1999) identified spring chinook salmon juveniles as the

species most at risk for direct predation by hatchery coho salmon smolts, this is discussed further in the specific effects section (4.2.3) below.

Potential direct and indirect predation impacts on listed UCR spring chinook salmon and UCR steelhead from chinook salmon releases are expected to be minimal because hatchery salmon are released as migration-ready smolts, during high flows in the spring, further limiting interaction with natural fish rearing in the action area. Finally, UCR spring chinook salmon smolts that are present downstream from the hatchery release locations should be of a large enough size during the April and May release period that direct predation by hatchery salmon is not likely.

The summer chinook salmon programs that release juveniles into the tributary basins (Wenatchee, Methow, and Okanogan) are designed to supplement the indigenous summer chinook salmon populations in those basins. Adult summer chinook produced through the programs will therefore contribute to natural summer chinook juvenile production. The progeny of these fish are likely to be sub-yearling migrants, and their presence as rearing fish in the basin is limited. Adverse impacts because of predation by progeny of hatchery-origin summer chinook spawners to listed juvenile UCR spring chinook salmon is likely to be low, assuming resource partitioning between fish species that have evolved sympatrically.

The programs considered in this Opinion releases only migration-ready, yearling juveniles into tributary waters, with the exception of Wenatchee sockeye salmon. Yearling spring chinook salmon released from the hatchery are expected to travel rapidly downstream at rates ranging from 5 to greater than 59 km/day (Dawley *et al.* 1986). The release of volitionally migrating smolts limits the duration of interaction between the hatchery fish and listed UCR spring chinook salmon and UCR steelhead juveniles rearing in areas adjacent to, and downstream of, the hatchery release location.

NMFS finds that the potential of predation on UCR spring chinook salmon and UCR steelhead by chinook salmon and sockeye salmon released from the proposed programs is not substantial due to the migration-ready status and quick exodus from UCR spring chinook salmon and UCR steelhead rearing areas.

4.1.7 Residualism

Spring chinook salmon, summer chinook salmon, sockeye salmon, and coho salmon released from hatcheries into tributary areas as yearling smolts do not have the same potential to residualize as steelhead. Standardization of the life history of these salmon species by producing yearling juveniles defers from the variability in growth and advent of smoltification evident in natural fish populations. The hatchery production strategies designed to release uniform sized juvenile salmon limit the likelihood for residualization of the fish released.

The coho reintroduction programs raise specific concerns about the potential adverse impacts of hatchery released coho on naturally produced UCR spring chinook salmon and steelhead. Snorkel surveys conducted by the Yakama Nation throughout the Chewuch River after the release of hatchery yearling coho observed 13 coho salmon that did not emigrate in 1998 (Dunnigan and Hubble 1998). Most of the coho smolts that residualized were in the middle portion of the survey reach and only one of the 13 was in the vicinity of other salmonid species (Dunnigan and Hubble 1998). Also, 20 hatchery coho remained in the lower Eightmile acclimation pond from which the fish were released. All 33 coho that failed to emigrate appeared to be less than optimal size for smolt outmigration. Snorkel surveys are also being conducted by the Yakama Nation personnel in the Wenatchee River basin to determine if coho

smolts residualize. Results from surveys in 2000 indicate that few hatchery coho salmon remain in the vicinity of the Wenatchee release areas post-release (Murdoch and LaRue 2002).

The potential of adverse effects from residual unlisted hatchery salmon species in the region appears to be low, and no impacts on UCR spring chinook salmon or UCR steelhead are anticipated.

4.1.8 Nutrient Cycling

Current escapements of natural origin and naturally spawning hatchery origin anadromous salmonids in the Columbia Basin are estimated at about 7 percent of the historic biomass (Cederholm *et al*. 1999). Artificial propagation programs in the basin add substantial amounts of fish biomass to the freshwater ecosystem. The potential to utilize the marine-based nutrients that are imported to freshwater ecosystems in the carcasses of hatchery returns may be of value for stimulating ecosystem recovery. Experiments have shown that carcasses of hatchery produced salmon can be an important source of nutrients for juvenile salmon rearing in streams (Bilby *et al*. 1998). Hatchery carcasses may also replace some of the nutrient deficit in riparian plant and terrestrial wildlife communities where natural-origin spawners are lacking.

Distributing carcasses after spawning at hatchery facilities may be incorporated into many of the artificial propagation programs evaluated in this opinion. Managers considering carcass outplants must follow disease control guidelines and should not transfer carcasses between drainages. Managers should also consider other habitat conditions of target streams including the presence of small woody debris that helps retain carcasses as they decompose, the likely natural density of spawner carcasses and the presence of nutrient enrichment such as agricultural runoff.

4.1.9 Masking

Under certain circumstances, artificially produced fish may lead to escapements of adult hatchery fish to natural spawning areas where they may intermingle with natural-origin fish of the same species. For many of the programs proposed, this is an explicit goal of the program. However, continuous annual escapements of the hatchery fish to natural spawning areas may confound the ability to determine the annual abundance of the natural-origin fish, if present and commingled with the hatchery fish. This situation may lead to an over-estimation of the actual abundance and productivity of the natural fish population, and as a corollary, a lack of ability to assess the health and production potential of habitat for the natural population. This latter factor exists because the hatchery fish might not be as successful in producing future generation in the natural environment. The abundance and productivity of the natural fish population, and the health of the habitat that sustains the natural fish, is therefore "masked" by the continued infusion of hatchery origin fish. Most of the proposed programs are not likely to result in any masking effect on UCR spring chinook salmon and UCR steelhead because of morphological differences between the listed species that allow accurate visual identification or adult run timing differences that distinguish the adult returns from UCR spring chinook salmon and UCR steelhead. Additionally, if summer chinook salmon return timing overlaps with UCR spring chinook salmon returns, the summer chinook salmon smolts released into tributaries are identifiable because their adipose fin is removed prior to release, whereas the UCR spring chinook salmon are adipose fin clipped. The proposed USFWS programs rearing non-native stock of spring chinook salmon have the potential to mask the productivity of listed UCR spring chinook salmon and is further discussed below.

4.1.10 Fisheries

Fisheries in the UCR basin are currently limited by the need to protect ESA-listed UCR spring chinook salmon and UCR steelhead. Fisheries in the migration corridor and ocean are also limited to protect these populations, and to minimize harvest impacts on other listed salmon and steelhead returning to other Columbia River basin and Snake River basin areas. NMFS evaluates and authorizes annual fisheries proposed by the co-managers in the action area each year through separate section 7 biological opinions. The WDFW and the Yakama Nation promulgated fisheries in Icicle Creek in 2000 to harvest surplus unlisted spring chinook salmon adults originating from Leavenworth NFH through separate section 7 consultations. These fisheries occurred in May near the Leavenworth NFH dam and in lower Icicle Creek. Icicle Creek fisheries for Leavenworth NFH are expected to continue in subsequent years. Impacts on listed spring chinook salmon are expected to be insubstantial in these hatchery-fish directed harvests, as the Icicle Creek return area is isolated from listed fish production areas in the Wenatchee River basin. Current, low external marking levels for Leavenworth NFH spring chinook salmon allowing for their differentiation from listed spring chinook hampers the ability to harvest returning adult fish in other regional areas. Proposed increased external marking proportions may increase opportunities for the beneficial use of returning Leavenworth NFH spring chinook salmon in fisheries. The new Yakama Nation coho salmon reintroduction program is currently experimental, and will not lead to substantial numbers of adult returns that might be targeted for harvest for the term of this Opinion.

Harvest actions outside the action area, such as in the ocean, mainstem Columbia River and other basin areas will be managed through the *U.S. v Oregon* and Pacific Fisheries Management Council (PFMC) planning and management processes, with guidance from NMFS.

Proposed releases of spring chinook salmon, summer chinook salmon, sockeye salmon, and coho salmon juveniles into the UCR basin are not expected to create any substantial harvest complications with listed species. NMFS involvement with the co-managers in the PFMC and *U.S. v Oregon* fishery planning processes will adequately limit harvest effects on listed salmon and steelhead. Proposals for future fisheries will continue to be addressed by NMFS through separate section 7 consultation processes.

4.1.11 Monitoring and Evaluation/Research

Listed UCR spring chinook salmon and UCR steelhead may be affected by foot, snorkel, and boat surveys conducted by the action agencies each year to enumerate adult salmonids on the spawning grounds and collect biological data on salmon carcasses. These activities could result in the temporary displacement or harassment of UCR spring chinook salmon and UCR steelhead. However, spawning surveys targeting these listed species have been previously authorized in permits 1203, 1115, 1119, and 1395 (NMFS 2002d, 2003b). In the analysis for each of those permits, NMFS concluded that spawning ground surveys were not likely to result in any long-term adverse effect on any of the populations or to the species as a whole. Spawner count data collected through the surveys are used to assess the status of salmon populations in the UCR region, the effectiveness of artificial propagation programs, and allow for management responses commensurate with run size decreases or increases. Information collected through the surveys includes observations regarding the distribution and timing of spawning of salmonids in the basins. These observations are combined with data from previous years to identify trends in escapement and to describe characteristics of the spawning populations. Biological data collected from carcasses include length, sex, scale and/or tissue sampling, snouts for CWT recovery, and assessment of egg voidance. These data are used to assess artificial propagation

program effectiveness, natural-origin spawner contribution, adult age at return, stray rates, and smolt-to-adult survival rates. Incidental take may occur in the form of temporary displacement. No UCR spring chinook salmon or UCR steelhead will be lethally taken. During most of the spawning surveys activities for summer chinook salmon, sockeye salmon and coho salmon, UCR spring chinook salmon are not present because they have completed spawning and have died of natural causes and UCR steelhead are in the process of returning to the basin and finding holding areas to stage for spawning which begins in late winter.

Activities associated with the surveys will include trained staff walking on the stream banks or in shallow river areas to count live and dead adult salmonid or using rafts to float river reaches where spawning has historically occurred. Snorkel surveys may also be used to count adult fish in these spawning areas. Float and snorkel surveys may occur throughout the river channel, but will focus on coverage of the transitional area between pools and riffles where the majority of spawning generally occurs. These surveys provide critical information about each artificial propagation program and the impacts on natural populations. They are not anticipated to result in any long-term or substantial adverse impacts on any of the populations or the UCR spring chinook salmon and UCR steelhead ESUs as a whole.

4.2 Specific Effects on UCR Spring Chinook Salmon

The specific effects that require additional detail from the preceding general effects analysis on the UCR spring chinook salmon ESU in the action area are evaluated in this section. Specific areas of concern include broodstock collection activities, genetic introgression risk from programs that rear unlisted spring chinook salmon, competition from those same programs and the coho reintroduction programs, and predation from artificially propagated coho, masking effects from unlisted spring chinook salmon programs, and potential monitoring and evaluation project impacts.

4.2.1 Broodstock Collection

Carson NFH stock spring chinook returning to Leavenworth NFH are trapped as volunteers to the hatchery from late May through mid-June. There is a potential that listed natural-origin spring chinook originating from other portions of the Wenatchee River watershed may also be trapped at the hatchery as volunteers. However, the number of listed spring chinook adults that are likely to return to Leavenworth NFH is low. Scale analysis of spring chinook adults collected at Leavenworth indicates that very few wild spring chinook escape to the hatchery (one was estimated to have been taken in 1994) (USFWS 1999).

Carson NFH-lineage spring chinook salmon returning to Entiat NFH are trapped as volunteers to the hatchery from late May through mid-June. There is a potential that May-June migrating listed natural-origin spring chinook salmon returning to the Entiat River may also be trapped at the hatchery as strays. If the run arrives in early May, the hatchery fish may be excluded from entering the trap and remain in the natural environment. The hatchery does not use a weir to direct fish into the ladder and trap, and natural-origin fish spawn mainly in (and home to) areas at least ten miles upstream of the hatchery. The number of listed spring chinook adults that recruit to the hatchery rather than spawn naturally in the Entiat River is likely to be very low.

The BPA/Yakama Nation coho salmon broodstock collection program proposed for Dryden and Tumwater Dams and "Dam 5" on Icicle Creek should not pose additional risk to listed spring chinook salmon, as the coho adults are proposed to be collected between September and December, much later than the May-June adult spring chinook migration period. The above

activities are not likely to affect listed juvenile spring chinook salmon due to the design and location of the broodstock collection actions.

The above trapping programs directed at summer chinook salmon, sockeye salmon, and coho salmon at Leavenworth NFH, Dam 5, and Dryden Dam are not likely to affect the listed UCR spring chinook salmon ESU.

4.2.2 Genetic

Impacts to listed UCR spring chinook salmon through are not anticipated as a result of the summer chinook salmon programs considered in this Opinion. Spring chinook salmon spawn in the Wenatchee and Methow River basins from late July through September, peaking about mid-August (WDF *et al*. 1993; Chapman *et al*. 1995a). Summer chinook salmon begin spawning in late September and end in early to mid-November, with peak spawning in October (Chapman *et al*. 1994a; WDF *et al*. 1993).

The proposed Carlton Pond summer chinook salmon program is not likely to affect the within population diversity of listed spring chinook salmon. Broodstock for the summer chinook program are collected at Wells Dam in late summer. Spring chinook salmon destined for the Methow River basin are unlikely to be encountered to a significant extent, or inadvertently incorporated as broodstock. Due to morphological differences between the spring and summer chinook races, WDFW staff are able to visually separate and pass upstream any spring chinook encountered during trapping at Wells Dam. The WDFW delays operation of the Wells Dam east ladder trapping site until July 10 to further minimize the likelihood for inadvertent retention of late-arriving Methow basin spring chinook.

Temporal separation in spawning time between the summer and spring races of chinook salmon minimizes the risk to listed spring chinook salmon of genetic introgression in the event that the hatchery summer chinook salmon stray into natural spring chinook spawning areas. Reduction in genetic diversity among listed spring chinook populations is not a significant risk for the artificial propagation programs rearing summer chinook salmon.

The Leavenworth NFH Carson-stock spring chinook salmon program has the potential to pose genetic risks to listed UCR spring chinook salmon. Returning Leavenworth NFH spring chinook salmon overlap in return and spawn timing with listed natural spring chinook salmon. Spawning of Carson-lineage spring chinook salmon occurs at the hatchery from mid-August until early September (USFWS 1999). As noted above, native spring chinook salmon in the Wenatchee River basin spawn from late July through September. Hatchery fish that stray into natural spring chinook salmon spawning areas may adversely affect the genetic diversity of the natural population if a significant level of spawning between the hatchery and natural origin fish occurs.

The risk posed by straying of Leavenworth NFH-origin adult spring chinook salmon to natural spring chinook salmon spawning areas in the Wenatchee River basin appears to be low. Leavenworth NFH spring chinook salmon are released into, and home back to, Icicle Creek, a Wenatchee tributary lacking a self-sustaining natural spring chinook salmon population. Also, homing of the fish to Icicle Creek provides separation of hatchery spawners from natural-origin spring chinook salmon produced in other tributaries, reducing the likelihood for interbreeding. From extant mark recovery information, Leavenworth NFH spring chinook salmon adults appear to exhibit a high fidelity to the hatchery release site. Few coded wire tagged hatchery fish have been recovered in the Wenatchee River basin outside of the hatchery (Chapman *et al*. 1995a; USFWS 1999). However, juvenile fish tagging proportions, and subsequent tagged adult spring

chinook salmon returns on which the low hatchery spring chinook salmon adult stray findings are based, have been low (~12 percent of the total spring chinook salmon production). Proposed, significant increases in the annual proportion of Leavenworth NFH spring chinook salmon yearlings marked (USFWS (1999) - 50 percent by the 2003 release year) will help corroborate this low stray rate assumption. With the information in hand, it is NMFS's opinion that straying of Leavenworth NFH-origin spring chinook salmon adults to areas outside of the Icicle Creek basin is low, and the risk of genetic introgression posed by the program to listed natural origin spring chinook salmon is low. Additional information gained from increased marking percentages for Leavenworth NFH release groups will allow for the reassessment of this opinion. New information regarding hatchery fish straying risks will also allow adaptive management of the Leavenworth NFH program if stray levels appear to be above expected low levels.

The Entiat NFH Carson-lineage spring chinook salmon program has the potential to pose genetic risks to listed natural spring chinook salmon. Returning Entiat NFH spring chinook salmon overlap in return and spawn timing with listed natural spring chinook salmon. Spawning of Carson-lineage spring chinook salmon occurs at the hatchery from mid-August until early September (USFWS 1999). Native spring chinook salmon in the Entiat River spawn upstream of the hatchery from late July through September. Hatchery fish that stray into natural spring chinook salmon spawning areas may adversely affect the genetic diversity of the natural population if a significant level of spawning between the hatchery and natural origin fish occurs.

Carcass recovery and sampling data had previously indicate that Entiat NFH spring chinook salmon do not tend to stray into natural spawning areas in the Entiat River (USFWS 1999; Carie 2000). The USFWS reports that no Entiat NFH-origin fish have been found on natural spawning grounds in the Entiat River in six years of carcass sampling (Cates 2000a; Carie 2000). Although evidence of straying to natural spawning areas using coded-wire tag recoveries is minimal, only 31 percent of the yearling spring chinook salmon released through the Entiat program have been marked in recent years. The majority of hatchery fish returning as adults are therefore indistinguishable from natural-origin spring chinook, absent scale pattern analysis sampling. Recent sampling in 2001 to the present, which included DNA sampling, indicate that stray rates of hatchery produced spring chinook salmon may be higher than early thought. Also, Entiat NFH fish stray to other hatcheries in the region (e.g., to Winthrop NFH in 1999), and marked Entiat NFH spring chinook salmon that bypass the Entiat River have been regularly encountered during WDFW's annual spring chinook salmon broodstock collection operations at Wells Dam (A. Murdoch, WDFW, pers. comm.).

Mass marking of spring chinook salmon yearlings released from Entiat NFH by the 2001 release year with an externally visible mark is proposed by USFWS. This increased fish marking provides an improved means to identify the hatchery fish and to separate them from listed spring chinook salmon at trapping locations and other hatcheries within the region. Mass marking will also improve the ability to monitor hatchery fish straying to natural spawning areas within the UCR spring chinook salmon ESU. Mark recovery information, and the collection of additional genetic stock identification data from Entiat NFH-origin and Entiat River natural spring chinook salmon, will help clarify concerns regarding genetic diversity within the system, and the effects of Entiat NFH spring chinook salmon straying on listed spring chinook. Additional DNA monitoring should be done as well as increased spawning grounds surveys undertaken to substantiate the genetic composition of spring chinook salmon in the Entiat River basin. New information in this area, may necessitate reinitiating consultation.

The Winthrop NFH Carson stock spring chinook salmon program has posed significant genetic risks to listed natural spring chinook salmon. Returning unlisted Winthrop NFH spring chinook

salmon overlap in return and spawn timing with listed indigenous-origin spring chinook salmon in the Methow River basin. Spawning of Carson stock spring chinook salmon occurs at the hatchery from mid-August until early September (USFWS 1999). This spawning date range may also be assumed for Winthrop NFH fish that stray into natural spawning areas. Native spring chinook salmon in the Methow River spawn in mainstem areas and tributaries from late July through September.

Significant concerns exist regarding straying and spawning of non-native Winthrop NFH spring chinook salmon in natural spring chinook salmon spawning areas within the Methow River basin (Myers *et al*. 1998). Genetic introgression risks to the native spring chinook salmon populations posed by straying Carson ancestry hatchery fish were identified as a major concern which led to the listing of UCR ESU spring chinook salmon as endangered (Myers *et al*. 1998; 64 FR 14308, March 24, 1999). In contrast to the Leavenworth NFH program, the Carson stock spring chinook salmon program at Winthrop NFH is not isolated. Non-native adult fish produced by the hatchery return directly to riverine areas that sustain naturally spawning, listed spring chinook salmon populations. The hatchery does not use a weir in the mainstem Methow River to direct returning adult fish into the hatchery, and attraction water to the trapping facility is low in volume relative to mainstem river flow. Because of its mainstem river location and lack of a fish weir, Winthrop NFH has no way of keeping its fish from straying into the natural spawning areas. Non-native Winthrop NFH-origin spring chinook salmon adults have therefore commonly spawned in the mainstem Methow River. The USFWS production of the Carson stock at Winthrop NFH has led to hatchery fish contribution levels to total Methow River natural spawning escapements estimated to be as high as 39 percent in some years (Myers *et al*. 1998). In addition, adult spring chinook salmon strays originating from Winthrop NFH have escaped to WDFW's Methow Hatchery where listed spring chinook salmon are produced as part of a stock recovery program. Straying of Winthrop NFH-origin Carson adult fish has resulted in the inadvertent incorporation of the non-native stock into the listed Methow "Composite" broodstock maintained at the WDFW hatchery. The effects of this straying on the genetic characteristics of the listed "composite" broodstock have been significant. For example, approximately 65 percent of the 1997 brood year Methow "Composite" adult return to Methow Hatchery in 2001 was estimated to be of Carson stock genetic lineage, based on an analysis of the origin of broodstock contributing to that brood year (D. Campton, USFWS, April 23, 2001 draft analysis). However, other brood years of Methow Composite have had significantly less Carson stock influence.

Given the above, it is likely that the natural Methow River mainstem spring chinook salmon population has some level of non-native hatchery fish ancestry, and is a composite of hatchery and natural origin fish as a result of interbreeding (WDF *et al*. 1993; BAMP 1998; Myers *et al*. 1998). The current genetic characteristics of the native and non-native Carson-origin spring chinook salmon populations in the Methow River, and the consequences of Carson stock production on the indigenous stocks, are addressed in a report distributed to NMFS and the Co-managers by the USFWS (Badgley 2000, with attached draft report by Don Campton, fish geneticist for USFWS).

The USFWS originally proposed to reduce the risk of continued genetic introgression posed by Carson stock spring chinook salmon straying by gradually phasing out releases of Carson stock smolts, supplanting production with smolts of listed spring chinook salmon stock-origin (USFWS 1999; Cates 2000a). Under this proposal, by 2005, the Carson stock would be supplanted entirely by releases of listed, indigenous-origin, Methow "Composite" stock hatchery spring chinook salmon developed and maintained through WDFW's Methow Hatchery program. To expedite phase-out of the Carson stock, USFWS reduced Carson stock releases sooner than proposed. In 2001, 177,000 listed Methow "Composite" stock yearlings and no Carson stock

yearlings were released at Winthrop NFH (D. Carie, USFWS, pers. comm.). The Winthrop NFH trap would continue to be operated during the phase-out period. Carson stock, and listed Methow "Composite" adult spring chinook salmon escaping to the hatchery would continue to be used as broodstock. Carson stock fish surplus to broodstock needs during the phase-out period would be provided to the Colville Tribes or to local food banks.

The original USFWS proposal for phasing out Carson stock production at Winthrop NFH was modified through the 2001 "Methow/Upper Columbia Agreement" (WDFW 2001). Under the agreement, effective 2001, the Winthrop NFH program will transition to the propagation of only listed Methow "Composite" spring chinook salmon stock. The last Carson stock adult returns to the hatchery as five year old fish will therefore occur in 2003. This approach will help forestall further genetic introgression risks to the listed spring chinook salmon populations that may result from Carson stock returns and straying to natural spawning areas or Methow Hatchery.

Detailed, supportive information regarding the need to phase-out use of the Carson-lineage spring chinook salmon stock at Winthrop NFH as a measure to protect the listed spring chinook salmon population is presented in a recent NMFS review and management recommendation document (NMFS 2001). The scientific basis for the hatchery stock management strategies applied to limit adverse genetic effects to listed salmon populations, including those proposed for Winthrop NFH, are described in an additional document prepared by NMFS Northwest Fisheries Science Center staff (Ford 2001). Information presented in these NMFS documents is summarized below.

In several scientific studies (e.g., Chilcote 1997; Reisenbichler and Rubin 1999), fish from non-native hatchery stocks have been shown to have poor spawning success in the natural origin compared to natural origin fish, even for programs that are capable of producing high returns to the hatchery or to fisheries. This is likely to also be the case with the Winthrop NFH Carson stock, which is not only not native to the Methow River, but has also been under domestication for over forty years. Current understanding of non-native hatchery fish performance and effects suggest that the Winthrop NFH Carson stock is more likely to harm than benefit the natural Methow River spring chinook salmon populations. Although Carson stock spring chinook salmon and their progeny will probably have some ability to reproduce in the natural origin, their reproductive success and survival will almost certainly be lower than the native fish. This means that over time the genetic attributes of the Carson-stock have the risk of being transferred to the native populations through interbreeding, reducing their survival and reproductive success. This process will be slow if only a few Carson-stock fish stray into natural spawning areas, but may occur rapidly if large numbers of Carson-stock fish were allowed to spawn with the native fish. The need to prevent further genetic introgression by limiting the straying of Carson-lineage spring chinook salmon into natural production areas supports the immediate phase out of the stock at Winthrop NFH.

The Methow "Composite" stock that will be used to supplant the Carson stock best represents the genetic lineage and diversity of the indigenous, natural Methow basin populations. Both the history of the stock and recent genetic data strongly suggest that the Methow Composite stock is more representative of native Methow River basin spring chinook salmon than is the Winthrop NFH Carson stock. The Methow Composite stock is, however, a mixture of at least two previously genetically distinguishable natural populations (from the Methow River mainstem and Chewuch Rivers) and certainly includes some degree of Carson-stock influence.

An additional component of the 2001 agreement (WDFW 2001) called for the cessation of adult spring chinook salmon trapping at Winthrop NFH. All adult fish returning as a result of

Winthrop NFH releases in 2001 will be prevented from entering the hatchery, and allowed to spawn naturally. Prior to the 2001 agreement, the majority of returning Carson stock adults were removed from the natural environment at the hatchery. The agreement to prevent returning fish from entering the hatchery and allowing all hatchery spring chinook salmon to spawn naturally responds to treaty tribal desires to expeditiously increase spring chinook salmon natural spawning numbers in the Methow River basin using available stocks, regardless of their origin. The proportion of the total naturally spawning spring chinook salmon population in the Methow River basin comprised by Carson stock fish will likely be significantly increased over recent year levels as a result of this agreement. The biological risk of this approach is that a relatively small number of indigenous-origin spawners in the basin could be overwhelmed by a relatively large number of non-native Carson stock spawners.

NMFS believes that genetic introgression risks to listed spring chinook salmon populations attendant with the allowance for all Winthrop NFH-origin Carson stock adults to spawn naturally may be ameliorated by several factors. First, it is hoped that adult fish prevented from entering Winthrop NFH will maintain a high fidelity to their release location. Returning fish may therefore have a tendency to spawn in the mainstem Methow River adjacent to or downstream of the Winthrop NFH outfall channel. Annual spawning ground surveys indicate that the mainstem river section downstream of the hatchery outfall supports a low proportion of the total naturally spawning spring chinook salmon escapement each year. The 1987-1999 annual mean spring chinook salmon redd count in this section of the river was 9, or 5.9 percent of the mean redd count of 152 recorded for the entire mainstem Methow River for this period (redd count data from H. Bartlett, WDFW, pers. com.). If the majority of returning Carson stock adults spawn in the mainstem river downstream of the hatchery, genetic introgression risks to the mainstem and tributary-spawning spring chinook salmon populations in the Methow River basin should be low. In 2001, Carson stock origin fish spawned predominately in the Methow River in close proximity to the hatchery facilities (Joel Hubble, pers. com. 2002).

In addition, based on recent research on the natural spawning success of hatchery-origin adult fish (e.g., Chilcote 1997; Reisenbichler and Rubin 1999), naturally spawning Carson stock spring chinook salmon can be expected to have poor spawning success in the natural origin. The Carson stock at Winthrop NFH has been under domestication for approximately 10 generations. Few progeny of naturally spawning Carson stock fish are expected to survive to adulthood, and any that do survive will be the result of a full generation of natural selection. The risk that the stock will prosper naturally, and increase genetic diversity reduction risks to listed spring chinook salmon in future years, is likely to be low.

Finally, NMFS believes that the short term adverse effects on listed spring chinook salmon resulting from the agreement to allow all Winthrop NFH Carson stock fish to spawn naturally in 2001 are adequately balanced by the long term genetic risk reduction benefits of the agreement achieved by prioritizing production of only listed, indigenous-origin smolts at Winthrop NFH. The risk that adverse among population diversity reduction effects on listed spring chinook salmon populations will be exacerbated by the forced escapement of Carson stock adult fish into natural spawning areas in 2001-2003 exists. This risk will be present through 2003, when the last Carson stock five year old adults from Winthrop NFH return (assuming the transition away from Carson stock smolt releases continues). However, NMFS believes that the 2001 & 2002 agreements are likely to reduce genetic risks to the listed Methow River spring chinook salmon populations more immediately than the previously agreed, gradual phase-out of Carson smolt releases at Winthrop NFH. Through the 2001 & 2002 agreements, and if no Carson stock smolts are released after 2001, non-native adult spring chinook salmon produced by the hatchery will

cease to return after 2003, instead of 2008 under the previous, proposed USFWS stock phase-out approach.

In past years when adult spring chinook salmon returns to the Methow River basin were low, USFWS' Winthrop NFH has relied on collections of spring chinook salmon adults trapped at Wells Dam to meet unlisted and listed spring chinook salmon broodstock needs. Volunteers to the hatchery, primarily of Carson stock, have also been used as broodstock. With transition of the program to the production of listed Methow "Composite" stock spring chinook, beginning in 2004, the majority of spring chinook salmon that return to the Methow River will be the listed stock. Listed Methow Hatchery spring chinook salmon adults have historically strayed into the Winthrop NFH trap. With the 2001 and 2002 agreements (WDFW 2001, NMFS 2002), spring chinook salmon adults will not be trapped at Winthrop NFH, and all fish will be prevented from entering the hatchery trap. Because no trapping will occur in 2001 and 2002, listed natural-origin spring chinook salmon will not be trapped at Winthrop NFH, nor incorporated into the hatchery broodstock.

4.2.3 Competition/Density Dependent Effects

Listed natural spring chinook salmon are present year-round in the Wenatchee and Methow tributary and mainstem areas. Spring chinook salmon fry emerge from the gravel in late winter or early spring at an average size of approximately 30 mm fl. The fry will disperse to the available habitat, with some fry immediately moving downstream to mainstem tributary areas for rearing. The spring chinook salmon range in size from 30-40 mm fl in the spring and average 54 mm fl in June. Spring chinook salmon migrating seaward as yearling fish between April and June average 87 to 127 mm fl (data summarized in Chapman *et al.*1995a).

For the species viewed as posing competition risks by SIWG (1984), spring chinook salmon, summer chinook salmon, and coho salmon yearling smolts released from the hatcheries by the action agencies in April and May likely encounter newly emerged, listed spring chinook salmon fry adjacent to the hatchery release sites. These release groups may also encounter spring chinook salmon fry in river reaches downstream of the release sites. Emigrating spring chinook salmon smolts in the action area may also be encountered during the hatchery fish emigration period. The SIWG (1984) identified a high risk that competition by hatchery-origin chinook salmon and coho salmon juveniles could have a substantial negative impact on productivity of natural chinook salmon juveniles in freshwater. The group identified hatchery sockeye salmon releases as posing a low risk of negative competitive effects in freshwater to natural chinook salmon and steelhead juveniles (SIWG 1984).

The majority of coho salmon juveniles released into the Wenatchee River basin are expected to emigrate rapidly, and soon after the fish volitionally leave the acclimation sites. Actively migrating coho salmon juveniles released mainly from the old Icicle Creek channel starting in late April, 2000 arrived at WDFW's Monitor out-migrant trapping location (approximately 20 miles travel distance) in 2.5 to 3.5 days, on average (Murdoch and LaRue 2002). Yearling coho salmon juveniles released on-station from lower Columbia River region hatcheries also have been shown to exit tributary waters quite rapidly. Coho yearlings released from Elochoman Hatchery reach the Columbia River mainstem - a distance of 9 miles - within 24 hours post-release (Fuss 1997). Chinook salmon yearlings released as actively migrating fish from WDFW and USFWS hatcheries emigrate and disperse from the release sites rapidly. The Wenatchee River basin hatchery chinook salmon programs considered in this Opinion also release migration-ready, yearling juveniles. These hatchery-produced juveniles are also expected

to emigrate seaward soon after liberation, vacating and dispersing from stream areas where natural juvenile fish may be present.

Fry and parr resulting from naturally spawning coho salmon have the potential to compete with listed steelhead and spring chinook salmon juveniles in the Wenatchee River basin. The following analysis of the potential competitive effects of natural coho production resulting from the reintroduction program was partially included in the NMFS 1999 Biological Opinion for the BPA/Yakama Nation coho salmon program (NMFS 1999a). That analysis is carried forth here to describe and evaluate the potential effects of the naturally-produced progeny of reintroduced coho salmon on the indigenous listed salmon and steelhead populations. It is recognized, however, that the BPA (1999) proposal incorporates only a limited number of life history cycles for coho salmon. Most returning coho salmon adults are proposed to be collected as "localized" hatchery broodstock over this period, and minimal natural production is expected.

Information suggests that juvenile coho salmon are behaviorally dominant in agonistic encounters with juveniles of other stream-rearing Pacific Northwest salmonid species, including chinook salmon, steelhead, and cutthroat trout (*O. clarki*). Dominant salmonids tend to capture the most energetically profitable stream positions (Fausch 1984, Metcalfe 1986), providing them with a potential survival advantage over subordinate fish. Stein *et al.* (1972) showed that coho salmon fry dominated fall chinook fry in laboratory raceways, which led to displacement of chinook salmon fry from habitats they used when coho salmon fry were not present. Taylor (1991) suggested that coho salmon fry are dominant in agonistic encounters with spring chinook salmon fry; when the two species were reared sympatrically, coho salmon displaced chinook salmon from the pool habitats.

The BPA/Yakama Nation's long term proposal is to stock coho salmon in the Wenatchee River basin at levels consistent with historic natural coho salmon densities, and based on parr and smolt carrying capacity estimates for the major basin tributaries (BPA 1999). To reduce potential adverse impacts on spring chinook salmon and steelhead in the upper tributaries, the BPA/Yakama Nation should focus their coho salmon releases in areas where impacts on the ESA-listed species will be minimal, such as Peshastin and Icicle Creeks. The proposed coho salmon release levels considered in this Opinion represent the initial, feasibility stage of the reintroduction effort. Release levels are designed to be those necessary to identify ecological risks to listed fish, coho salmon broodstock requirements to meet desired production levels, and survival of out-of-watershed stocks (BPA 1999). Therefore, on the short term, and for the duration of the program considered in this Opinion, the numbers of coho salmon that are progeny of naturally spawning coho salmon will likely be very low and well below the estimated juvenile coho salmon carrying capacity of Wenatchee basin tributaries.

The BPA (1999) estimated that the number of coho salmon adults returning to the Wenatchee River basin as a result of the proposed annual release of 1,000,000 juveniles would be approximately 1,000. However, returns in 2000 and 2001 have fluctuated widely. The preliminary smolt-to-adult survival rate estimate for the 1998 and 1999 brood releases in the Wenatchee River were 0.21 percent (about 1,500 fish), and 0.17 percent (334 fish), respectively (Murdoch and LaRue 2002). Dunnigan *et al.* (2001) estimated that, based on planned coho salmon release sites and levels, adult coho salmon returns to the Wenatchee River watershed upstream of Tumwater Dam (where the majority of listed spring chinook salmon and steelhead production occurs) may range from a low of 66 fish in 2001 to a high of 2,396 in 2004. Coho salmon escapements at these levels would range from 1 to 37 percent of the historic natural coho escapement level to the basin, estimated to be 6,000 to 7,000 fish.

The majority of the coho salmon juveniles proposed for planting in the basin will be released from the old Icicle Creek channel, adjacent to Leavenworth NFH. Through an examination of CWT recoveries for hatchery coho salmon, Vander Haegen and Doty (1995) reported that from 0 to 12.4 percent of adult coho salmon originating from on-station releases from Lower Columbia River region hatcheries were recovered in areas other than the watershed where the fish was reared. They generally found that stray rates for hatchery coho salmon reared and released on-station were comparable to natural fish. The expected high fidelity of returning adult coho salmon adults to the vicinity of Leavenworth NFH, where the coho salmon will be reared and acclimated for four to six weeks, should limit the likelihood for natural spawning by these fish, and the resultant production of progeny that may pose a competitive risk to listed juvenile spring chinook salmon and steelhead.

Density-dependent effects resulting from competition between two different species can still be severe at densities well below the carrying capacity of the habitat. However, estimating carrying capacity is extremely difficult, and even an abundant population may not be "fully seeded" for all life history stages (Lestelle *et al.* 1996; Moussalli and Hilborn 1986). Therefore, interactions between coho salmon and listed UCR spring chinook salmon should be monitored and evaluated regardless of the estimated carrying capacity or historic run size. The BPA/Yakama Nation (BPA 1999; YN *et al*. 2002) recognized the need for studies in the basin to evaluate the effects of naturally producing coho salmon through competition on listed fish, when the numbers of coho in the target basins were adequate to make such studies possible.

Hatchery-origin adult salmon from these programs that may home to, or stray into, UCR spring chinook salmon spawning areas during the egg incubation periods may pose an elevated risk to listed fish productivity. Competition for redd sites or egg mortality posed by hatchery-origin fish redd superimposition are concerns. Superimposition of redds by later spawners kills or removes previously deposited eggs from the gravel, and has been identified as an important source of salmon mortality in some areas.

Protected UCR spring chinook salmon adults spawn from late July through September in the Wenatchee River basin. Spawning areas in the basin include the Chiwawa River (Rkm 0 to 58.0), Nason Creek (Rkm 0 - 25.4), White River (Rkm 10.3 to 23.0), the Little Wenatchee River (Rkm 4.3 to 11.4), and the upper most reaches of the Wenatchee River.

Adult coho salmon resulting from the BPA/Yakama Nation reintroduction program may spawn naturally in Icicle Creek, or in areas near the acclimation pond release sites on Nason Creek, and in future years, the Chiwawa River, Little Wenatchee River, Brender Creek, and Chumstick Creek during November and December (BPA 1999). The number of adult coho salmon returning to the Wenatchee River basin and allowed to spawn naturally upstream of Tumwater Dam will need to be monitored and possible limited to ensure that the coho salmon are not superimposing redds over previously deposited ESA-listed spring chinook salmon redds. As a conservation measure, the number of coho allowed to spawn naturally in Nason Creek should be limited to no more than 50 percent of the total number of UCR spring chinook salmon that returned to Nason Creek (Tynan and Weitkamp 2001).

The use of non-native stock spring chinook salmon in the Entiat and Winthrop NFHs programs poses a higher risk of competition with listed UCR spring chinook salmon which may affect listed natural fish productivity through competition for redd sites and redd superimposition. The natural population interim abundance target is 500 and 2,000 spring chinook salmon adults in the Entiat and Methow Rivers, respectively.

Historic USFWS data indicates that few returns from Entiat NFH stray in most years. However, more recent years data indicate increased straying (Hamstreet and Carie 2003). Considering that total redd counts have ranged from 13 to 218 (1994 to 2002 data) (Hamstreet and Carie 2003) it is unlikely that density dependent and competition effects are substantial in the Entiat River.

The five year geometric mean (1997-2001) of natural origin spawners in the Methow River population was 358. The estimated total adult return to Methow Basin from Winthrop NFH releases for that same period of time was 1,167 salmon. Depending on where the hatchery produced spring chinook spawn in the basin, some adverse impacts on the listed stock is possible. Spawning ground surveys to count redds and sample carcasses indicate that most Winthrop NFH origin spring chinook salmon spawn in the mainstem Methow River near the hatchery outlet and that natural origin listed spring chinook salmon spawn higher up in the Methow River and its tributaries, the Chewuch and Twisp Rivers (Hubble and Crampton 2000). Additionally, the transition from Carson stock to the local Methow River stock in order to contribute to the recovery of the listed stock result in NMFS finding that density dependent and competition effects are not anticipated to adversely impact the UCR spring chinook salmon ESU.

4.2.4 Predation

Coho salmon predation studies conducted on the Yakima River in 1998, 1999, and 2001, by the Yakama Nation (2002) suggest that predation by hatchery coho salmon juveniles on spring chinook fry is low. The Yakama Nation, in coordination with WDFW, conducted studies in 2000 to assess the effects of Wenatchee basin hatchery coho salmon predation on unlisted natural summer chinook salmon fry. Coho salmon juveniles liberated from the old Icicle Creek channel and Butcher Creek were trapped at WDFW's Monitor screw trap site, and sampled for stomach contents. Preliminary results of the study indicate that the incidence of summer chinook salmon fry predation averaged 0.0241 fry per coho salmon smolt captured. Based on this rate, estimated trapping facility, and assumptions of emigrating coho salmon smolt residence time in the river (assumed to be 7 or 16.5 days), the Yakama Nation initially estimated that from 145,705 to 343,447 summer chinook fry may have been consumed by coho salmon juveniles in the mainstem river above Monitor post-release. However, the predation rate used to derive this range may overestimate actual fry consumption, as trap operation procedures confined the fry with coho salmon in trap live boxes for three or more hours. This practice may have exposed the summer chinook salmon fry to predation levels higher than actual natural levels. In addition, the summer chinook salmon fry preyed upon by the coho salmon were relatively abundant in the release area, and the proportion consumed of the total summer chinook salmon fry population present in the Wenatchee basin was likely quite low. Also, results in 2000 may have been affected by the presence of a large number of summer chinook salmon redds at the mouth of Icicle Creek (immediately below the main coho salmon release site). There may therefore have been a concentration of summer chinook salmon fry available for predation in this area that may have biased the predation results towards higher than typical levels.

The Yakama Nation study at Monitor may be used to indicate summer chinook salmon fry predation effects only. However, due to their extremely depressed status in the Wenatchee basin, spring chinook salmon fry are much lower in abundance than summer chinook salmon fry in the vicinity of the study area. Also, the majority of spring chinook salmon fry are likely to remain in tributary areas upstream of the Icicle Creek and Butcher Creek coho release sites where they may not be exposed to predation. However, additional, proposed coho salmon acclimation sites in the listed spring chinook production areas may pose predation risks to spring chinook salmon fry. Further predation/interaction studies in the watershed are proposed, including trap operation on Nason Creek, sockeye salmon -directed sampling in Lake Wenatchee, and river snorkel surveys,

to help identify specific predation effects of the hatchery coho salmon release program on listed spring chinook salmon fry in the important tributary production areas. Releasing coho salmon juveniles in areas with little ESA-listed spring chinook salmon and steelhead production such as Peshastin, Icicle, and Brender Creeks would reduce risks of adverse impacts on these protected species while still allowing the assessment of the coho salmon reintroduction program.

All of the Wenatchee River basin hatchery chinook salmon and coho salmon programs considered in this Opinion release migration-ready, yearling juveniles. The majority of coho salmon juveniles released into the Wenatchee River are expected to emigrate rapidly after liberation from acclimation sites. Data collected by the Yakama Nation for old Icicle Creek channel releases in 2000 supports a rapid downstream migration of liberated coho salmon juveniles (Murdoch and LaRue 2002). Yearling spring chinook salmon released from Leavenworth NFH are also be expected to travel rapidly downstream. Yearling chinook salmon juveniles released from up-river Columbia basin areas have been shown to travel downstream at rates ranging from 5 to greater than 59 km/day (Dawley *et al.* 1986). The WDFW targets the release of uniform sized hatchery juveniles (a coefficient of variation (CV) of <10 percent around the average fish size is applied) as an additional measure to ensure that the majority of the hatchery population is migration-ready.

The production of natural coho salmon juveniles by naturally spawning hatchery adult coho that could pose elevated predation risks to listed fish fry and fingerlings in the region should be limited over the next five years. Approximately 66-2,400 adult coho may return to the Wenatchee River basin as a result of the proposed annual release of 1,000,000 coho juveniles. The BPA (1999) estimates that fewer than half of any returning coho will spawn naturally. Expected, low adult coho returns to natural areas, and the proposed collection of most returning coho adults as hatchery broodstock over that period should result in the natural production of few coho juveniles. Also, coho natural spawning that does occur is expected to take place removed from (Icicle Creek), or downstream of (lower Nason Creek), spring chinook spawning areas in the basin. Icicle Creek is the predominant release site for the first years of the reintroduction program, and most adult coho will return to that location for the term of this Opinion. Differences in habitat preferences by natural-origin coho and natural spring chinook may further minimize the risk of predation on spring chinook salmon fry by natural-origin coho. Over the short term, predation risks to listed spring chinook salmon fry should be limited. The Yakama Nation plans to conduct studies (e.g., Nason Creek trapping) that will help gauge the effects of coho predation in upper tributary areas important to spring chinook salmon production. The results of these studies should be used to guide activation and management of the other proposed coho salmon acclimation sites in the region.

4.2.5 Masking

Unlisted spring chinook salmon adults produced through Leavenworth NFH program return to the Wenatchee River basin and spawn at the same time as listed UCR spring chinook salmon. Mark recovery work indicates that returning Leavenworth NFH spring chinook salmon adults have a low tendency to stray to areas outside of their Icicle Creek release location. High fidelity of returns to Icicle Creek, where there is no listed spring chinook salmon population, limits the likelihood that the program leads to substantial masking effects. The USFWS proposes to increase the external marking rate for juvenile spring chinook released from the hatchery as a measure to improve the ability to detect stray fish in natural spawning areas. Increased external marking will also allow for differentiation of the hatchery fish from natural fish during spawning ground and carcass recovery surveys, improving the accuracy of natural fish population censuses. Also limiting the risk of masking effects on listed spring chinook salmon populations is the

release of fish into a tributary lacking listed fish, and the removal of surplus adult returns through Icicle Creek fisheries, or at the hatchery for beneficial uses. NMFS finds that the risk of masking effects on listed spring chinook salmon through the Leavenworth NFH program is adequately limited through the above management practices and measures.

Unlisted spring chinook salmon adults produced through the Entiat NFH program return to the Entiat River and spawn at the same time as listed natural-origin spring chinook salmon in the Basin. Carcass recovery and spawning ground studies by USFWS indicate that returning Entiat NFH spring chinook salmon adults have a low tendency to stray to areas within the Entiat River basin outside of their hatchery release location. However, as previously mentioned, the low marking rate may confound the ability to identify hatchery produced spring chinook salmon on the spawning grounds. Stray Entiat NFH-origin adult fish are recovered at Wells Dam each year, and some adult fish are also recovered at hatcheries in the Methow River Basin. The USFWS proposes to increase the external marking rate for juvenile spring chinook released from the hatchery as a measure to improve the ability to detect stray Entiat NFH fish at these trapping locations and in natural spawning areas. Increased external marking of the hatchery fish will also allow for differentiation of the hatchery fish from wild fish during trapping operations, and through spawning ground and carcass recovery surveys, improving the accuracy of wild fish population censuses. Also limiting the risk of masking effects on listed spring chinook salmon populations is the removal of surplus hatchery adult returns to the hatchery for beneficial uses. The risk of masking effects on listed spring chinook salmon through the Entiat NFH program should be adequately limited through these practices and measures.

Unlisted spring chinook salmon adults produced through the Winthrop NFH program return to the Methow River and spawn at the same time as listed spring chinook salmon. Returning Winthrop NFH-origin spring chinook salmon adults have a high tendency to stray into natural spawning areas in the Methow River mainstem. Significant proportions of the total annual naturally spawning fish population in the mainstem river in some years have been of Winthrop NFH-origin. This situation has confused managers' ability to determine the abundance status of listed spring chinook in the mainstem river.

Phase out of unlisted Carson spring chinook stock production at Winthrop NFH, and cessation of unlisted spring chinook returns to the facility after 2004 should help address the masking issue. The listed Methow composite stock used to supplant Carson stock for production is considered of closer lineage to naturally spawning fish in the Methow River mainstem. The risk of masking effects on listed spring chinook salmon through the Winthrop NFH program is adequately limited through the planned stock transition.

4.2.6 Monitoring and Evaluation

The BPA/Yakama Nation (BPA 1999; YN 2001a) propose to operate a rotary screw-type trap, and potentially electroshockers, in Nason Creek in the Wenatchee River basin to collect juveniles released from the Butcher Creek acclimation site. The trapping study is proposed to determine predation rates on listed spring chinook salmon fry. The Nason Creek screw trap operation may lead to the incidental capture, handle and release of about 500 fry and 1,000 smolt listed spring chinook salmon juveniles, with a potential lethal take of 10 fry and 20 juveniles (YN *et al*. 2002). The loss of 30 juvenile UCR spring chinook salmon is not likely to substantially affect the UCR spring chinook salmon ESU.

The Yakama Nation do not expect to encounter any UCR spring chinook salmon during tow or trawl net component of the proposed Lake Wenatchee sockeye salmon/coho salmon interaction

study. Adequate equipment and measures are included for tow net sampling to minimize harm to listed juvenile fish that are incidentally collected. These measures include use of a cod-end bucket on the terminus of gear to provide a sanctuary for entrained fish, and careful handling, sampling, and release procedures proposed for application. Potential use of mid-water trawl gear as an alternative to tow nets poses an elevated risk to listed juvenile fish that may be encountered. Fish captured in trawl nets have a greater potential for injury and mortality. The number of listed fish encountered is expected to be very small. The juvenile coho salmon radio-telemetry portion of the Yakama Nation study is not expected to affect listed juvenile fish.

The BPA/Yakama Nation (1999) also proposes to conduct snorkel surveys to monitor coho salmon emigration in the watershed, and electro-shocking for presence-absence study purposes, or potentially, to collect additional coho salmon for the Nason Creek predation study. Snorkeling may temporarily displace rearing listed fish from stream areas, for brief periods of time. Electro-shocking in Nason Creek may result in incidental take in the form of capture, handle and release of 150 juvenile/smolt spring chinook salmon, and the lethal take of 15 juveniles/smolts from the ESU. The Yakama Nation's compliance with NMFS electro-fishing guidelines (NMFS 1998b) should adequately limit the risk of adverse effects on listed fish encountered during proposed electro-fishing and could result in a numerically small lethal take of UCR spring chinook salmon.

Predation and species interaction studies proposed by the Yakama Nation in Nason Creek and in Lake Wenatchee are not likely to affect listed adult fish. The proposed Nason Creek screw trap and Lake Wenatchee tow net operations occur prior to the adult spring chinook salmon migration and spawning periods, and adult fish are therefore not expected to be encountered.

4.3 Specific Effects on UCR Steelhead

The specific effects that require additional detail from the preceding general effects analysis on the UCR steelhead ESU in the action area are evaluated in this section. Specific areas of concern include operation of the Leavenworth NFH facilities, broodstock collection activities, and competition/density dependent effects from the coho salmon artificially propagated programs, and potential monitoring and evaluation project impacts.

4.3.1 Operation of Hatchery Facilities

A barrier to upstream fish passage associated with structures in Icicle Creek placed in association with the Leavenworth NFH program has been in place since 1940, and may adversely affect listed steelhead productivity in the Wenatchee River basin. This barrier to upstream fish passage is being addressed through a separate forum (the Icicle Creek Restoration Project EIS process), including USFWS, NMFS, state, tribal, Icicle Creek Watershed Council, and other private participants. NMFS expects that the EIS process will lead to the application of a preferred alternative allowing passage of adult and juvenile fish above the barrier, potentially benefitting steelhead recovery in the Wenatchee River basin and reducing the risk to the listed steelhead ESU. The preferred alternative will be evaluated by NMFS for effects on listed fish through a separate section 7 consultation. The effects on listed fish of water withdrawal from upper Icicle Creek for municipal, agricultural, and hatchery use, and the operation of the water intake structure for water withdrawals from Icicle Creek, will also be addressed by NMFS through a separate section 7 consultation. Although an effects analysis and jeopardy determination for this portion of the Leavenworth NFH operation will not be rendered in this Opinion, it is NMFS ' expectation that free upstream passage for listed UCR steelhead juveniles and adults must be provided at the Leavenworth NFH Dam. The Icicle Creek does not support listed UCR spring

chinook salmon and no adverse impacts are expected to result from the operation of the Leavenworth NFH facility on UCR spring chinook salmon.

The hatchery water intake structure for Leavenworth NFH in Icicle Creek is currently not screened to exclude juvenile ESA-listed fish in compliance with NMFS screening criteria, due to the location of the intake in a high velocity, exposed section of the creek. As mentioned previously, the USFWS, with potential funding from the BOR, is investigating options for the modification of this structure to achieve full compliance with these criteria (USFWS 2000a). It is NMFS ' opinion that, although fish may enter the water intake and be displaced downstream, the system functions adequately to reduce the risk of injury and mortality, or other harm to any anadromous fish that may be entrained, and that the risk of substantial adverse effects on listed Wenatchee basin steelhead is minimal. The present lack of access to anadromous fish to the area of the intake beyond the few steelhead and Carson-lineage spring chinook salmon passed upstream for the radio-tagging study also supports this opinion. However, NMFS acknowledges the future, enhanced need to modify the intake structure to minimize the risk of juvenile steelhead entrainment when upstream fish passage at the hatchery dam is provided.

Structures, including screens, maintained in the old Icicle Creek channel during rearing to contain acclimating coho salmon may prevent, if present, listed juvenile and adult fish from accessing the channel. The issue of appropriate acclimation and rearing sites for coho salmon in the Icicle Creek watershed needs to be addressed in the long-term management plan. The BPA/Yakama Nation are working with local watershed groups to reach consensus regarding acceptable rearing locations for coho salmon in the Icicle Creek watershed at, or in the vicinity of, Leavenworth NFH.

The overall number of listed steelhead incidentally captured, handled, and released each year in unlisted salmon trapping operations is currently low, and under 100 fish. The proposed operation schedules for the summer chinook salmon trapping programs exclude the majority of migrating adult steelhead. The duration of weekly and daily trapping at proposed broodstock collection locations is limited to allow free passage of adult steelhead upstream without delay or handling. BPA (1999) has proposed to expand the trapping durations at Tumwater Dam to collect adult coho salmon for broodstock, leading to increased adult steelhead take levels. The USFWS trapping programs directed at unlisted hatchery spring chinook salmon stocks are confined to the hatcheries, which rely on volunteers to the hatchery traps. Listed UCR steelhead adult stray rates to these hatchery traps will be low. Listed steelhead adult returns to Wells Hatchery are expected. Wells Hatchery is a production location for this listed species, and steelhead takes at the hatchery were previously authorized under section 10 permit 1395. Risk aversion measures applied at the trapping facility during broodstock collection, including minimal holding and handling of incidentally encountered steelhead, should reduce the risk of harm. Therefore, unlisted salmon broodstock collection operations as proposed are anticipated to have minimal adverse impacts on UCR steelhead.

4.3.2 Broodstock Collection

The BPA/Yakama Nation have proposed to modify trap operational times and durations at Dryden and Tumwater Dams from those proposed by WDFW to accommodate coho salmon broodstock collection objectives (BPA 1999). The WDFW is currently permitted under section 10 permit 1395 for the directed collection of 208 steelhead in the Wenatchee River (Dryden and Tumwater traps combined) and 395 steelhead from the run at large arriving at Wells Dam. This steelhead take is authorized by NMFS for collection as broodstock for the Wells Hatchery-based listed steelhead supplementation program. Increased trap operational days proposed by BPA will

lead to estimated incidental takes (through additional capture, handling and release) of 25 to 30 steelhead at each location during trapping operations to collect coho broodstock (BPA 1999).

The Dryden and Tumwater Dam traps encounter a small number of adult steelhead each year during operations directed at the collection of summer chinook and sockeye salmon broodstock. The average annual numbers of adult steelhead that are captured, handled and released are 11 at Dryden Dam (1992-96 average) and 23 at Tumwater Dam (1996 data only), respectively (WDFW 1999d). The WDFW applies measures to minimize steelhead capture levels, and the risk of harm to any incidentally captured steelhead. These measures include the allowance for unrestricted passage of steelhead at Tumwater Dam when the trap is not being actively operated, continuous monitoring during trapping at Tumwater Dam, minimal holding times in trap live boxes at Dryden (< 24 hours), and careful handling and release upstream of all steelhead captured.

Few listed steelhead are reported to be encountered during trapping for unlisted spring chinook salmon at Leavenworth NFH each year (Cooper *et al*. 2002). On average 15-20 adult steelhead are trapped and released back into the river annually (B. Cates, USFWS, February 8, 1999). These steelhead are usually un-spawned adult steelhead that have entered the Leavenworth NFH fish ladder during spring chinook trapping periods, in May and early June. These steelhead are released unharmed. Some steelhead are trapped at the hatchery and passed upstream above the hatchery dam for a migration and habitat utilization study in Icicle Creek. This steelhead-directed study has been authorized by NMFS under a separate ESA permit process.

Few listed steelhead are reported to be encountered during trapping for unlisted spring chinook salmon at Entiat NFH each year (Cooper *et al*. 2002). Spawned out steelhead may enter the Entiat NFH fish ladder during the May through early June spring chinook salmon trapping period. Any steelhead encountered are released unharmed into the Entiat River.

The BPA/Yakama Nation's proposed collection of coho salmon adults returning to the Leavenworth NFH ladder and old Icicle Creek channel between September and December has a small potential for additional captures of steelhead adults. The number of steelhead that may be incidentally collected by the Yakama Nation staff in the ladder and at "Dam 5" at the base of the old Icicle Creek channel should be very low. During USFWS snorkel surveys in September, no adult steelhead have been observed in the pool below the hatchery barrier adjacent to where coho salmon broodstock will be collected. Juvenile steelhead or resident rainbow trout are observed during these surveys on occasion. While it is likely that the mainstem Wenatchee River does hold steelhead at the time coho salmon are proposed to be collected as broodstock (September - December), adult steelhead should rarely be present in Icicle Creek during that period. Trapping by BPA/Yakama Nation at the hatchery dam to collect coho broodstock is therefore not expected to lead to substantial impacts on listed steelhead.

The BPA/Yakama Nation also proposes to collect coho salmon broodstock at the Dryden Dam traps on a five to seven day per week frequency (BPA 2002 - ltr to Rob Jones dated Feb. 11, 2002; YN *et al*. 2002) through the first week of December. The WDFW currently operates the Dryden Dam traps seven days per week until November 14th, so the proposed BPA/Yakama Nation coho program could increase the number of steelhead encountered. Steelhead encountered may be collected as broodstock for the Wenatchee steelhead program as authorized under permit 1395. If steelhead are not retained for broodstock they would be released unharmed upstream of the trap site and the overall impact to the protected population is anticipated to be negligible.

The increased frequency of trapping proposed by BPA to collect coho at Tumwater Dam trap during the September through December period will likely lead to increases above current levels in the number of adult steelhead that will be incidentally captured, handled and released. The WDFW currently proposes to operate the trap to collect summer chinook and steelhead (direct take authorized by NMFS under section 10 permit 1395 (NMFS 1998a)) as broodstock three days per week, eight hours per day during the September and November period to limit handling of steelhead, and to prevent potential problems with steelhead migrational delay and fall-back. The BPA proposes to increase the frequency of trapping at Tumwater Dam to four days per week in November and December, which could result in the additional capture and handling of 25 to 30 adult steelhead. The BPA proposes to staff the Tumwater Dam trap with the Yakama Nation staff full-time. The BPA (1999) also indicates that all listed fish captured during the coho-directed broodstock collection program, including steelhead, will be removed from the trap and released immediately upstream. In years of high coho salmon returns, it may be recommended to remove all coho encountered at Tumwater Dam to restrict the number of adult coho salmon on the spawning grounds to reduce potential impacts on spring chinook salmon redds which are built earlier in the year.

The above trapping programs directed at summer chinook, sockeye, and coho salmon at Leavenworth NFH, Dam 5, and Dryden Dam may affect, but are not likely to adversely affect listed UCR ESU steelhead due to low numbers encountered, and the implementation of impact reduction measures during trapping. Trapping proposed to collect sockeye, summer chinook, and coho broodstock at Tumwater Dam (WDFW 2000) may affect, but are also not likely to adversely affect listed UCR ESU steelhead. Low numbers of steelhead are encountered through operation of the trap at the frequency proposed, and listed fish may pass the dam freely when the trap is not being actively operated.

The hatchery programs reviewed in this Opinion collect as broodstock, spawn, and propagate unlisted salmon. Listed salmon and steelhead incidentally encountered through the programs, and not transferred for use as broodstock in previously authorized stock recovery programs, are released at the point of capture. No substantial broodstock removal effects, including numerical reduction or selection effects, on listed UCR steelhead will occur through the proposed broodstock collection programs.

4.3.3 Competition/Density-Dependent Effects

Listed UCR steelhead are present year round in the Wenatchee, Methow, and Okanogan River basin tributary and mainstem areas. Steelhead fry imerge and disperse to downstream areas in late summer and fall at a size of 30-33 mm fl. Steelhead emigrate seaward as age 2+ (43.2 percent) or 3+ (46.4 percent) smolts (Peven 1990) during April and May at an average size of 163 to188 mm (Chapman *et al.* 1994b).

As described above in Section 4.2.3, coho salmon smolts released into the Wenatchee River basin are expected to emigrate rapidly, soon after the fish volitionally leave the acclimation sites, thereby limiting the potential for negative impacts on rearing natural origin steelhead. The large size of the hatchery fish relative to the natural fry and fingerlings present at the time of the releases also decreases the likelihood for competition for the same food resources by the hatchery and natural fish. The larger, seaward migrating hatchery smolts will also tend to use different habitat than rearing steelhead and spring chinook salmon fry and fingerlings that may be encountered.

The Wenatchee summer chinook salmon program is designed to supplement the indigenous summer chinook salmon population in the Wenatchee River and the release sites are well below the spring chinook salmon spawning and early rearing areas. Adult summer chinook salmon produced through the program will therefore contribute to the naturally spawning summer chinook salmon population. The risk of adverse competitive effects posed by progeny of hatchery-origin summer chinook salmon spawners to listed juvenile spring chinook salmon and steelhead is likely to be low, assuming resource partitioning between fish species that have evolved sympatrically in the Wenatchee River system and the spatial separation of the species. Fish species that evolved sympatrically in the UCR basin have developed slight differences in habitat use that tend to reduce opportunities for interaction, including competition for food resources, rearing space, and spawning areas.

Natural spawning by straying Leavenworth NFH spring chinook salmon adults appears to be low, and the risk that progeny of such spawners will adversely affect listed juvenile fish through competition is therefore low.

As previously mentioned, information suggests that juvenile coho salmon are behaviorally dominant in agonistic encounters with juveniles of other stream-rearing Pacific Northwest salmonid species, including chinook salmon, steelhead, and cutthroat trout (*O. clarki*). Dominant salmonids tend to capture the most energetically profitable stream positions (Fausch 1984, Metcalfe 1986), providing them with a potential survival advantage over subordinate fish. Aggressive interaction between coho salmon and steelhead fry that result in competitive displacement of steelhead trout are well documented (Hartman 1965, Allee 1974). Fraser (1969) observed that the survival rate of steelhead living sympatrically with coho salmon declined slightly as coho salmon densities increase. However, where interspecific populations have evolved sympatrically, chinook salmon and steelhead have evolved slight differences in habitat use patterns that minimize their interactions with coho salmon (Nilsson 1967; Lister and Genoe 1970; Taylor 1991). Along with the habitat differences exhibited by coho salmon and steelhead, they also show differences in foraging behavior. Peterson (1966) and Johnston (1967) reported that juvenile coho salmon are surface oriented and feed primarily on drifting and flying insects, while steelhead are bottom oriented and feed largely on benthic insects. However, Fraser (1969) stated that the instantaneous growth rate of steelhead declines with increasing coho salmon density during sympatry.

Steelhead and coho salmon share a common ancestry and similar habitat requirements. Recent research by Merz and Vanicek (1996) found that in a two year study of salmon and steelhead juvenile diets in the American River, California, the diets of the two species was substantially the same. Furthermore, in the mainstem Columbia River, Muir and Emmett (1988) found migrating chinook salmon, coho salmon, and steelhead juveniles all ate predominately the same food item - *Corophium salmonis*. Therefore, interspecific competition is expected to occur and may strongly influence the behavior, growth, and survival of the two species when they occur sympatrically in nature. The level of competition and influence on behavior, growth and survival is dependent upon the food source being limited in the mainstem Columbia River.

Coho salmon may have a competitive advantage over steelhead when they coexist. Juvenile coho salmon tend to emerge from the gravel earlier then steelhead, which allows them to establish territories and reach larger sizes than steelhead of the same age class (Berejikian 1995). Both laboratory and stream studies indicate that these species use different stream microhabitats. In the absence of coho salmon, steelhead use more of the water column and more pool habitat than when coho salmon are present (Hartman 1965; Allee 1974; Bugert and Bjornn 1991). In the

presence of coho salmon, age-0 steelhead generally occupy the shallower, faster water of riffles and pool slopes, while coho salmon occupy the deeper water of pools (Bugert and Bjornn 1991).

In-stream segregation between coho salmon and steelhead appears to be both actively maintained and adaptive (Nilsson 1967). Their habitat segregation is consistent with interspecific morphological variation: juvenile steelhead are more fusiform in shape than coho salmon and therefore better able to cope with higher water velocities (Bisson *et al.*1988). These differences may reduce competition and facilitate partitioning of stream resources during low summer flows in streams when competition is most intense (Hard 1996). Because of their different morphology and habitat use, it is expected that stream characteristics will be primary determinants of interactions between these species: steelhead are expected to thrive better in the presence of coho salmon in streams with higher gradients and velocities, while steelhead are likely to diminish in streams with lower gradients and velocities (Hard 1996; Stelle 1996).

Recent investigations by the Yakama Nation in the Wenatchee River basin indicate that the artificially propagated coho salmon released in Nason Creek and Icicle River in 1999, 2000, and 2001 have emigrated out the Wenatchee system quickly, and therefore have had minimal opportunity for competition or density dependent effects on occur (Murdoch and LaRue 2002).

The BPA/Yakama Nation's long term proposal is to stock coho salmon in the Wenatchee River basin at levels consistent with historic natural coho salmon densities, and based on parr and smolt carrying capacity estimates for the major basin tributaries (BPA 1999). To reduce potential adverse impacts on spring chinook salmon and steelhead in the upper tributaries, the BPA/Yakama Nation should focus their coho salmon releases in areas where impacts on the ESA-listed species will be minimal, such as Peshastin and Icicle Creeks. The proposed coho salmon release levels considered in this Opinion represent the initial, feasibility stage of the reintroduction effort. Release levels are designed to be those necessary to identify ecological risks to listed fish, coho salmon broodstock requirements to meet desired production levels, and survival of out-of-watershed stocks (BPA 1999). Therefore, on the short term, and for the duration of the program considered in this Opinion, the numbers of coho salmon that are progeny of naturally spawning coho salmon will likely be very low and well below the estimated juvenile coho salmon carrying capacity of Wenatchee basin tributaries.

4.3.4 Monitoring and Evaluation

The BPA/Yakama Nation (BPA 1999; YN 2001a) propose to operate a rotary screw-type trap, and potentially electroshockers, in Nason Creek in the Wenatchee River basin to collect smolts released from the Butcher Creek acclimation site. The trapping study is proposed to determine predation rates on listed spring chinook salmon fry. The Nason Creek screw trap operation may lead to the incidental capture, handle and release of about 500 fry and 1,000 smolt listed spring chinook salmon juveniles, with a potential lethal take of 10 fry and 20 smolts (YN *et al*. 2002). The Yakama Nation estimate that 500 juvenile/smolt steelhead may be incidentally captured, handled and released, and 10 may be lethally taken during the Nason Creek screw trap operations.

The Yakama Nation do not expect to encounter any spring chinook salmon or steelhead during tow or trawl net component of the proposed Lake Wenatchee sockeye salmon/coho salmon interaction study. Adequate equipment and measures are included for tow net sampling to minimize harm to listed juvenile fish that are incidentally collected. These measures include use of a cod-end bucket on the terminus of gear to provide a sanctuary for entrained fish, and careful handling, sampling, and release procedures proposed for application. Potential use of mid-water

trawl gear as an alternative to tow nets poses an elevated risk to listed juvenile fish that may be encountered. Fish captured in trawl nets have a greater potential for injury and mortality. The number of listed fish encountered is expected to be very small. The juvenile coho salmon radio-telemetry portion of the Yakama Nation study is not expected to affect listed juvenile fish.

The BPA (1999) also proposes to conduct snorkel surveys to monitor coho salmon emigration in the watershed, and electro-shocking for presence-absence study purposes, or potentially, to collect additional coho salmon for the Nason Creek predation study. Snorkeling may temporally displace rearing listed fish from stream areas, but is not expected to exert substantial adverse effects. Electro-shocking in Nason Creek may result in incidental take in the form of capture, handle and release of 150 juvenile/smolt spring chinook salmon and 150 juvenile/smolt steelhead, and the lethal take of 15 juveniles/smolts of each protected species. The Yakama Nation's compliance with NMFS electro-fishing guidelines (NMFS 1998b) should adequately limit adverse effects on listed fish encountered during proposed electro-fishing.

Predation and species interaction studies proposed by the Yakama Nation in Nason Creek and in Lake Wenatchee are not likely to affect listed adult fish. The proposed Nason Creek screw trap and Lake Wenatchee tow net operations occur prior to the adult spring chinook salmon migration and spawning periods, and adult fish are therefore not expected to be encountered.

4.4 Cumulative Effects

Cumulative effects are defined in 50 CFR §402.02 as "those effects of future State, tribal, local or private actions, not involving Federal activities, that are reasonably certain to occur in the action area considered in this biological opinion." Future Federal actions, including the ongoing operation of hatcheries, fisheries, and land management activities, are not considered within the category of cumulative effects for ESA purposes because they require separate consultations pursuant to Section 7 of the ESA after which they are considered part of the environmental baseline. Future State, tribal, local, or private actions within the action area are described for NEPA purposes in the EIS (NMFS 2003) regarding the implementation of the three HCP agreements. NOAA Fisheries evaluated these actions to determine whether or not they would meet the requirements of its implementing regulations. Those actions which are most notable include Washington State TMDL (total maximum daily load) development and implementation, Washington State legislation to enhance salmon recovery through tributary enhancement programs, and recent human population trends in the action area. However, after considerable review, NOAA Fisheries has determined that these actions cannot be deemed reasonably likely to occur based on its ESA implementing regulations.

The Endangered Species Consultation Handbook describes this standard as follows:

> "Indicators of actions 'reasonably certain to occur' may include, but are not limited to: approval of the action by State, tribal or local agencies or governments (e.g., permits, grants); indications by State, tribal or local agencies or governments that granting authority for the action is imminent; project sponsors' assurance the action will proceed; obligation of venture capital; or initiation of contracts. The more State, tribal or local administrative discretion remaining to be exercised before a proposed non-Federal action can proceed, the less there is a reasonable certainty the project will be authorized."

There are, of course, numerous non-Federal activities that have occurred in the action area in the past, which have contributed to both the adverse and positive effects of the environmental

baseline. This step of the analysis for application of the ESA Section 7(a)(2) standards requires the consideration of what of those past activities are "reasonably certain to occur" in the future within the action area.

First of all, any of these actions that involve Federal approval, funding, or other involvement are not considered "cumulative effects" for this analysis (see ESA definition, above). This Federal involvement will trigger ESA Section 7(a)(2) consultation in the future. Once the consultation on those actions is completed the effects may be considered part of the environmental baseline, consistent with the ESA regulatory definition of "effects of the action" (50 CFR §402.02). Thus, for example, state efforts to improve water quality in compliance with the Federal Clean Water Act would not be considered because of the involvement of the EPA, until separate ESA consultations are completed. Others examples include irrigation water withdrawals involving the

USFS (right-of-way permits for irrigation canals) or agricultural practices that receive Federal funding through the U.S. Department of Agriculture.

Next, actions that do not involve Federal activities must meet the "reasonably certain to occur" test for NOAA Fisheries to consider their effects in this Opinion. Recognizing that this is a narrower standard than used for NEPA purposes, not all of the actions identified in the EA may be considered as "cumulative effects" for this ESA Section 7(a)(2) consultation. In reviewing the actions identified in cumulative effects analysis of the EA, after eliminating from consideration those with Federal involvement, NOAA Fisheries finds that currently few, if any, of the future adverse or beneficial State, tribal or private actions qualify for consideration in this analysis as "cumulative effects."

Therefore, when evaluating the status of the listed species, including their likelihood of survival and recovery, NOAA Fisheries concludes that most of the factors for the decline of these species are not eligible for consideration in determining whether the authorization of incidental take under this HCP is likely to jeopardize their continued existence. Thus the future abundance and productivity of the listed UCR steelhead and UCR spring-run chinook salmon, against which the effects of this action are considered, are likely to be improved, although to an unknown or possibly minor extent, over those reflected by the historical trends under the environmental baseline.

4.5 Integration and Synthesis

The proposed actions may result in incidental take of listed UCR spring chinook salmon and UCR steelhead. The applicants propose protective measures, and NMFS further limits incidental take with conditions to be included in permit 1347 to minimize the extent of take. The above analysis suggests that species and behavioral differences between sockeye salmon, summer chinook salmon, coho salmon, and the listed UCR spring chinook salmon and UCR steelhead largely reduce potential adverse impacts.

In particular, risks associated with broodstock collection activities are minimal. The return timing and duration of sockeye salmon, and limited spawning and rearing areas of sockeye salmon in comparison to the listed species ESUs result in minimal interaction between sockeye salmon and the listed ESUs, and don't adversely affect their habitat. The adult return timing, and spacial and temporal differences of summer chinook compared with the listed ESUs reduces the potential risk from summer chinook programs. The proposed coho salmon program broodstock trapping timing largely coincides with UCR steelhead migrations. However, at most trapping sites, activities are ongoing that target the collection or sampling of UCR steelhead which have

been previously evaluated and authorized under ESA section 10(a)(1)(A) permit process (NMFS 2003).

No intake structures are associated with these operations. NMFS finds that the operation of hatchery facilities in the Wenatchee River basin with regard to water intake systems are not likely to pose a substantial risk to the UCR spring chinook salmon and UCR steelhead ESU.

Genetic risks are non-existent from sockeye salmon and coho salmon because of species differences. Genetic risk from summer chinook salmon programs are minimal due to spatial and temporal differences between the two chinook salmon races. Masking effects are not likely to occur because physical differences allow biologist to accurately identify the different species and the different chinook races where adult co-occur. Nutrient cycling impacts are expected to be mostly positive effects, increasing the food resources for listed species in the tributaries and potentially enhance the general health of the aquatic ecosystem. Monitoring and evaluation projects are crucial to increasing our understanding of artificial propagation programs, and their effects on listed and unlisted species, and will be carried out in a manner which minimizes adverse impacts on UCR spring chinook salmon and UCR steelhead.

Potential adverse impacts on juvenile UCR spring chinook salmon and UCR steelhead include impacts from the operation of the hatchery facilities, competition/density dependent effects, predation, and disease transfers. Hatchery facilities in the UCR generally employ techniques to minimize risks to listed species. They follow fish health protocols developed by regional co-managers, obtain and follow water withdrawal permits which limit surface water intakes, adhere to conditions of applicable NPDES water quality permits for water discharged from their facilities, and have implemented hatchery reform measures where possible.

Competition/density dependent effects and predation impacts are minimized for most of the programs by releasing only migration ready smolts which migrate out of the action area quickly. The sockeye salmon program releases juvenile sockeye in the late summer and fall at a size that is unlikely to prey on listed UCR spring chinook salmon or steelhead that could be rearing in Lake Wenatchee through the winter. The Wenatchee River basin coho program releases a small number of fry coho as part of a study designed to specifically investigate predation and competition impacts of the coho programs on the listed species.

Increased risks are posed by spring chinook salmon programs that rear non-native stock of spring chinook salmon. These programs proposed several strategies to limit or reduce adverse impacts. The Leavenworth NFH program promotes spatial separation between the non-native artificially propagated program and the listed UCR spring chinook program. Monitoring of the adults through scale analysis and CWT analysis at all the UCR basin hatchery facilities, carcasses sampled during spawning ground surveys, and harvest fishery sampling all generally support this conclusion and continued monitoring as proposed will help refine this analysis.

The Entiat NFH poses increased risk, although historic information suggested that this program also functioned in a manner to spatially separate the non-native artificially propagated spring chinook from the natural origin listed stock. However, increased monitoring is warranted which will be reflected in the program's annual reports, and may lead to reconsideration of the risks of this program. The Winthrop NFH has not been able to spatially separate the non-native stock and is in the process of transitioning the program to using the listed UCR spring chinook stock for the program. This program would be expected to aid in the recovery of the ESA listed UCR spring chinook salmon stock and operate as a conservation program after complete stock transition.

Monitoring of adult salmonids associated with all of the proposed programs would be conducted at trap sites incidental to authorized activities such as broodstock collection. Observation of adult salmonids on spawning grounds and sampling of dead carcasses pose minimal displacement or harrassment risks because either listed UCR spring chinook and UCR steelhead are not present at the time of these activities or similar activities directed toward the listed species are authorized under the ESA through separate processes, such as permit 1395 for UCR steelhead.

5 CONCLUSIONS

NMFS' approach for determining whether the proposed actions are likely to jeopardize the continued existence of ESA-listed salmonids or destroy or adversely modify designated critical habitat is based on an analysis of the existing or potential risk of hazards posed by the actions. NMFS has considered the analysis presented above and the likelihood for survival and recovery of the listed salmon and steelhead ESUs under the environmental baseline in making its jeopardy determination.

After reviewing the current status of listed UCR steelhead and UCR spring chinook salmon, the environmental baseline for the action area, the effects of the proposed artificial propagation programs in the UCR basin, and cumulative effects, it is NMFS' determination that the federal artificial propagation programs proposed for operation of funding by the USFWS and BPA in the UCR basin are not likely to jeopardize the continued existence of these listed ESU's or to destroy or adversely modify their habitat.

In addition, after reviewing the current status of listed UCR steelhead and UCR spring chinook salmon, the environmental baseline for the action area, the effects of the proposed artificial propagation programs in the UCR basin, and cumulative effects, NMFS concludes that the issuance of ESA section 10 incidental take permit 1347, including conditions as described above, for the artificially propagated programs proposed by the WDFW, the Chelan PUD, and the Douglas PUD is not likely to jeopardize the continued existence of the listed ESUs or to destroy or adversely modify their habitat.

6 INCIDENTAL TAKE STATEMENT

Section 9 of the ESA and federal regulation pursuant to section 4(d) of the ESA prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harm is further defined by the USFWS to include substantial habitat modification or degradation that results in death or injury to listed species by substantially impairing behavioral patterns, including breeding, feeding, or sheltering. Harass is defined by the USFWS as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to substantially disrupt normal behavior patterns which include, but are not limited to, breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity.

Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered to be prohibited taking under the ESA provided that such taking is in compliance with the terms and conditions of an incidental take statement (ITS).

The measures described below are non-discretionary, and must be undertaken by the action agencies so that they become binding conditions of any grant or permit issued to the applicant, as appropriate, in order for the exemption in section 7(o)(2) to apply. The action agencies have a continuing duty to regulate the activity covered by this ITS. If the action agencies (1) fail to assume and implement the terms and conditions or (2) fail to require the applicant to adhere to the terms and conditions of the ITS through enforceable terms that are added to the permit or grant document, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the agencies must report the progress of the action and its impact on the species to NMFS as specified in the ITS. [50 CFR §402.14(i)(3)].

An ITS specifies the impact of any incidental taking of endangered or threatened species. It also provides reasonable and prudent measures that are necessary to minimize impacts and sets forth terms and conditions with which the action agency must comply in order to implement the reasonable and prudent measures.

6.1 Amount or Extent of Take

The proposed actions are expected to result in the incidental take of listed salmon and steelhead in the Columbia River basin. A quantifiable take may occur during adult broodstock collection activities and some investigational activities for the unlisted artificial propagation programs. Tables 6-10 detail the estimated annual takes for activities where available. The incidental take of listed adult UCR spring chinook salmon and UCR steelhead most often will be in the form of capture, handling, and subsequent release of protected species. For activities that pose lethal threats to individuals, the estimated take level is provided. During most broodstock collection activities, retention of steelhead encountered is authorized for artificial propagation programs under separate section 10(a)(1)(A) permits.

Table 6. Expected annual ESA-listed adult UCR spring chinook salmon and steelhead take levels during USFWS operated UCR region unlisted spring chinook salmon broodstock trapping activities.

Species	Leavenworth NFH	Winthrop NFH	Entiat NFH
Spring chinook	< 10 (few)	[a]	< 10 (few)
Steelhead	20	< 10 (few)	<10 (few)

[a] *ESA-listed spring chinook capture at Winthrop NFH is authorized under section 10(a)(1)(A) permit 1300*

Table 7. Expected annual ESA-listed adult UCR spring chinook salmon and steelhead take levels during the Yakama Nation operated UCR region unlisted coho salmon broodstock trapping activities.

Species	Icicle River Dam 5	Priest Rapids	Dryden Dam	Tumwater Dam	Wells Dam East/West
Spring chinook	0	0	0	0	0
Steelhead [a]	0.5 %	3.5 %	5.0 %	3.5 %	4.5 %/4.5%

[a] *These take levels are in addition to take authorized to WDFW in permit 1395.*

Table 8. Expected annual ESA-listed adult UCR spring chinook salmon and steelhead take levels during WDFW operated UCR region unlisted salmon broodstock trapping programs.

Species	Priest Rapids	Dryden	Tumwater Dam	Wells
Spring chinook	0	0	< 10	<10 [a]
Steelhead [b]	10	11	23	19

[a] *Spring chinook encountered in the Wells Dam traps during summer chinook collection are shunted upstream without handling.*

[b] *Steelhead takes at the Dryden, Tumwater, and Wells Dam traps are authorized under section 10 permit 1395.*

Table 9. Expected annual ESA-listed adult UCR spring chinook salmon and steelhead take levels during YN weir operation in various UCR creeks.

Species	Brender Creek juvenile/adult	Beaver Creek juvenile/adult	Chumstick Creek juvenile/adult
Spring chinook			
capture, handle, release	0/0	0/0	0/0
lethal	0/0	0/0	0/0
Steelhead			
capture, handle, release	200/20	150/15	200/20
lethal	0/0	5/0	5/0

Table 10. Expected annual ESA-listed juvenile UCR spring chinook salmon and steelhead take levels during the Yakama Nation smolt trap monitoring of unlisted coho salmon smolt emigration activities.

Species	Eggs/fry	Juvenile/smolt
Spring chinook		
capture, handle, and release	500	1,000
lethal	10	20
Steelhead		
capture, handle, and release	0	500
lethal	0	10

Table 11. Expected annual ESA-listed juvenile UCR spring chinook salmon and steelhead take levels during the Yakama Nation monitoring of unlisted coho salmon juvenile interactions and impacts on growth of listed species using electroshocking techniques.

Species	Eggs/fry	Juvenile/smolt
Spring chinook		
capture, handle, and release	0	300
lethal	10	30
Steelhead		
capture, handle, and release	0	300
lethal	0	30

In the absence of the exact numbers of listed salmon and steelhead expected to be incidentally taken as a result of juvenile fish releases, NMFS has relied on a qualitative approach to limit incidental impacts on listed species. NMFS will monitor release numbers and locations to

determine compliance with the following reasonable and prudent measures and terms and conditions.

6.2 All Agency Reasonable and Prudent Measures

The following reasonable and prudent measures are provided to minimize and reduce the anticipated level of incidental take associated with the proposed artificial propagation programs:

1. The Action Agency shall manage their programs to minimize the risk of adverse demographic, ecological, and genetic effects on listed salmon and steelhead, including potential interbreeding of unlisted, hatchery-origin salmon and listed salmon, in the UCR basin.

2. The Action Agency shall coordinate the production of unlisted salmon with other fishery co-managers and other hatchery production programs in the UCR region.

3. The Action Agency shall apply external and/or internal marks to at least a portion of each hatchery release group for monitoring, evaluation and stock management purposes.

4. The Action Agency shall monitor and evaluate their respective artificial propagation programs in the UCR basin.

5. The Action Agency shall reduce potential negative impacts on listed salmon and steelhead in the UCR basin from physical operation of their respective artificial propagation facilities, including associated trapping locations.

6.3 All Agency Terms and Conditions

To carry out these reasonable and prudent measures, the following terms and conditions shall be implemented by the action agencies and their contractors.

<u>Program management, fish handling, hatchery facility operations, monitoring and evaluations activities</u>

1. Activities that encounter steelhead that are not authorized by other permits shall be limited to the levels indicated in Tables 6 through 11 of this Opinion. The action agencies shall report any occurrence in which this level is exceeded to NMFS in the monthly and annual report.

2. All action agencies shall manage adult artificially propagated stray rates to the lowest level achievable. For non-indigenous-origin salmon, stray rates should not exceed 5 percent of the annual natural-origin population size in the receiving stream. For within ESU-origin stocks out-planted for fishery augmentation/mitigation programs, unlisted salmon stray rates should be managed to not exceed 5 percent to 30 percent of the annual natural-origin population. The actual proportion allowed within this range will depend on the genetic compatibility of the straying artificially propagated stock with the natural population.

3. In the event that circumstances, such as unanticipated, higher-than-expected fecundity, or high egg-to-fry survival rates, lead to the inadvertent possession of salmon substantially in excess (>110 percent) of program production levels specified above, then surplus eggs

or fish shall be culled from the population in a manner consistent with achieving program goals.

4. The Action Agency is responsible for the actions of any individual operating under the authority of this permit. Such actions include capturing, handling, and releasing any ESA-listed species authorized to be incidentally taken by this permit.

5. The Action Agency must ensure that all ESA-listed species are handled carefully. Should NMFS determine that a procedure provided for under this permit is no longer acceptable, the Action Agency must immediately cease such activity until an acceptable substitute procedure is identified and approved by NMFS.

6. Measures shall be applied to ensure that artificially propagated chinook salmon juveniles released will be ready to actively migrate to the ocean. To meet this condition, fish must be released at a uniform size and state of smoltification that ensures that the fish will migrate seaward without delay after release. Variance from this smolts-only release requirement shall only be allowed in the event of an emergency, such as flooding, water loss to raceways, or vandalism, that necessitates early release of ESA-listed steelhead to prevent catastrophic mortality. Any emergency releases made by the action agencies shall be reported immediately to the NMFS Salmon Recovery Division in Portland.

7. The Action Agency must allow any NMFS employee or representative to accompany field personnel while they conduct authorized activities.

8. The Action Agency are responsible for obtaining all other federal, state, and local permits/authorizations needed for the proposed activities.

9. The Action Agency shall operate and manage the artificial propagation programs including following impact minimization measures as proposed in this section 7 Biological Opinion.

10. To the extent possible without imposing increased risk to listed species, the Action Agency shall enumerate and identify marks and tags on all anadromous species encountered at adult and juvenile trapping sites. This information shall be included in either an annual brood program report or a monitoring and evaluation report submitted to NMFS.

11. In trapping operations directed at the collection of broodstock, the Action Agency shall apply measures that minimize the risk of harm to listed salmon and steelhead. These measures include, but are not limited to: limitations on the duration (hourly, daily, weekly) of trapping in mainstem river areas to minimize capture and handling effects on listed fish; limits on trap holding duration of listed fish prior to release; application of procedures to allow safe holding, and careful handling and release of listed fish; and allowance for free passage of listed fish migrating through trapping sites in mainstem and tributary river locations when those sites are not being actively operated.

12. All traps that have the potential to incidentally capture listed UCR spring chinook salmon or UCR steelhead shall be checked and have the fish removed at least daily.

13. If water temperature at adult trapping sites exceeds 21 C (69.8 F), the trap operation shall cease pending further consultation with NMFS to determine if continued trap operation poses substantial risk to ESA-listed species that may be incidentally encountered.

14. The Action Agency shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during trapping. The Action Agency shall carefully handle and immediately release upstream incidentally captured listed UCR spring chinook salmon and UCR steelhead adults that are not intended for use as broodstock in concurrently operated and otherwise authorized listed stock recovery programs.

15. The Action Agency shall ensure that water intakes into artificial propagation facilities be properly screened in compliance with 1995 NMFS screening criteria and as per the 1996 addendum to those criteria (NMFS 1996). As an alternative, they shall comply with transitional criteria set forth by NMFS in 1999 for juvenile fish screens constructed prior to the establishment of the 1995 criteria (NMFS 1996), to minimize risks to listed salmon and steelhead. The Action Agency shall inspect and monitor the water intake screen structures at their hatchery facilities to determine if listed salmon and steelhead are being drawn into the facility; the results of this monitoring shall be included in annual reports.

16. The Action Agency shall implement the "Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State" (NWIFC and WDFW 1998) and Pacific Northwest Fish Health Protection Committee (PNFHPC 1989) guidelines to minimize the risk of fish disease amplification and transfer, and to ensure that artificially propagated fish would be released in good health.

17. The Action Agency shall conduct hatchery operations and monitor hatchery effluent in compliance with applicable National Pollutant Discharge Elimination System (NPDES) (EPA 1999) permit limitations.

18. Visual observation protocols must be used instead of intrusive sampling methods whenever possible. This is especially appropriate when merely ascertaining the presence of anadromous fish. Snorkeling and streamside surveys will replace multi-pass electro-fishing procedures whenever possible.

19. The Action Agency must coordinate with other co-managers and researchers to ensure that no unnecessary duplication and/or adverse cumulative effects occur as a result of the Action Agency's activities.

20. The Action Agency may conduct spawning ground and carcass surveys to assess the distribution and impact of artificially propagated salmon on the natural-origin populations.

Reports

NMFS contact for all reports: NMFS - Salmon Recovery Division
525 NE Oregon Street, Suite 510
Portland, Oregon 97232
Phone: (503) 230-5407
Fax: (503) 872-2737

1. The Action Agency must notify the Salmon Recovery Division of NMFS as soon as possible, but no later than two days after, any authorized level of take is exceeded or if such an event is likely. The Action Agency must submit a written report detailing why the authorized take level was exceed or is likely to be exceeded.

2. The Action Agency shall update and provide to the Salmon Recovery Division of NMFS by December 15th of each year, the projected hatchery releases by age class and location for the coming year.

3. The Action Agency shall provide annual reports that summarize numbers, pounds, dates, tag/mark information, locations of artificially propagated fish releases, and monitoring and evaluation activities that occur within the hatchery environment, and adult return numbers to the UCR basin for each program. The Action Agency shall ensure collection and reporting of the coefficient of variation around the average (target) release size immediately prior to their liberation from the acclimation sites as an indicator of population size uniformity and smoltification status. Reports shall also include any preliminary analyses of scientific research data, any problems that may have arisen during conduct of the authorized activities, a statement as to whether or not the activities had any unforeseen effects, and steps that have been and will be taken to coordinate the research or monitoring with that of other researchers. Unless otherwise noted in the specific terms and conditions, the reports shall be submitted by January 31st, of the year following release (i.e., brood year 2002, release year 2003, report due January 2004) to the Salmon Recovery Division of NMFS.

4. The Action Agency must provide plans for future projects and/or changes in sampling locations or enhancement/research protocols and obtain approval from the Salmon Recovery Division of NMFS prior to implementation of such changes.

5. Adult return information shall include the most recent annual estimates of the number and proportion of artificially propagated fish on the spawning grounds, and the number and location of artificially propagated adults that were recovered outside the release areas. Adult return information and results from monitoring and evaluation activities outside the hatchery environment should be included in the annual report or a separate report. If a separate report on monitoring and evaluation activities conducted outside the hatchery environment is prepared, it shall be submitted by August 31st, of the year following the monitoring and evaluation activities (i.e., surveys conducted in 2003, report due August 2004) to the Salmon Recovery Division of NMFS.

6. The Action Agency shall develop annual broodstock collection and spawning protocols for each artificial propagation program operated. Protocols should be coordinated with the co-managers and must be submitted to the Salmon Recovery Division of NMFS by April 15th for spring chinook salmon programs and June 15th for coho salmon programs of the collection year.

7. The Action Agency must report the take of any ESA-listed species not included in this permit when it is killed, injured, or collected during the course of enhancement/research activities. Notification should be made as soon as possible, but no later than two days after the unauthorized take. The Action Agency must then submit a detailed written report of the non-permitted take. Pending review of these circumstances, NMFS may suspend enhancement/research activities.

Penalties and Sanctions

1. The Action Agency may not transfer or assign this incidental take statement to any other person as defined in Section 3(12) of the ESA. This incidental take statement ceases to be in effect if transferred or assigned to any other person without NMFS' authorization.

2. If an Action Agency violates any permit term or condition, they will be subject to any and all penalties provided by the ESA.

3. The Action Agency, in effectuating the take authorized by this incidental take statement, are considered to have accepted the terms and conditions set forth herein and must be prepared to comply with the provisions of this incidental take statement, the applicable regulations, and the ESA.

4. The Salmon Recovery Division, NMFS, may amend the provisions of this incidental take statement after reasonable notice to the Action Agency.

5. 50 CFR Section 222.23(d)(8) allows NMFS to charge a reasonable fee to cover the costs of issuing this incidental take statement under the ESA. The fee for this incidental take statement has been waived.

6. Any falsification of annual reports or records pertaining to this incidental take statement is a violation of this incidental take statement.

7. Under the terms of the regulations, a violation of any of the terms and conditions of this permit will subject the Action Agency, and/or any individual who is operating under the authority of this permit, to penalties as provided for in the ESA.

6.4 Agency Specific Terms and Conditions

In addition to the all agency terms and conditions the following agency specific terms and conditions shall be implemented by the action agencies and their contractors:

6.4.1 U. S. Fish and Wildlife Service

6.4.1.1 Leavenworth NFH Spring Chinook Program

1. The USFWS shall limit annual yearling spring chinook salmon smolt production from Leavenworth NFH to not exceed 1,625,000 fish, for release in April or May.

2. The USFWS shall increase adipose fin-clipping of spring chinook salmon yearling releases from Leavenworth NFH. In release year 2003, at least 50 percent or 810,000 spring chinook shall be externally marked.

3. The USFWS shall develop long-term solutions for fish passage issues associated with Leavenworth NFH facilities and operations through the on-going Icicle Creek Restoration Project EIS process. As an outcome of this process, NMFS expects that the completion of the Icicle Creek Restoration Project process will lead to passage of at least listed steelhead, and potentially salmon adults and juveniles, into that portion of Icicle Creek upstream of the Leavenworth NFH barrier.

4. The USFWS shall immediately provide adult steelhead passage for unspawned steelhead above the hatchery barrier dam on Icicle Creek. To meet this requirement, the USFWS shall pass, by, sanctuary net, listed adult steelhead trapped in the fish ladder at Leavenworth NFH upstream of the hatchery barrier. The requirement shall apply until upstream passage for listed steelhead in Icicle Creek is provided through modifications or methods developed as an outcome of the on-going Upper Icicle Creek Restoration process.

5. The USFWS shall coordinate with NMFS , BIA, WDFW, and the Yakama Nation to develop and implement operational practices that provide for the effective removal and best use of Carson stock spring chinook adult returns to Icicle Creek and to the Leavenworth NFH trap that are surplus to annual egg take needs. For 2001 through 2005, beneficial uses of surplus unlisted spring chinook salmon may include their use for the Omak Creek spring chinook salmon reintroduction program, harvest in Icicle Creek fisheries, distribution for tribal ceremonial and subsistence use, and distribution to food banks. Outplanting into Peshastin Creek may also be a potential use of surplus unlisted spring chinook, if appropriate monitoring of spawning activity and juvenile production will also be conducted.

6.4.1.2 Entiat NFH Spring Chinook Program

1. The USFWS' shall limit annual production of spring chinook salmon smolts at Entiat NFH to not exceed 400,000 yearlings, for release in April or May.

2. The USFWS shall coordinate with WDFW to monitor and evaluate straying levels of Entiat NFH-origin spring chinook adult salmon to other regional hatcheries and trapping locations, and to natural listed salmon and steelhead production areas.

3. Prior to 100 percent external marked Entiat NFH returns to the UCR region, the USFWS shall coordinate with other WDFW to identify stray Entiat NFH spring chinook salmon adults via scale pattern analysis at Wells Dam and Methow Hatchery. Entiat NFH spring chinook identified at Methow Hatchery will be removed and trucked to Entiat NFH, or otherwise culled.

4. The USFWS shall apply an externally visible mark to 100 percent of the Carson NFH-lineage spring chinook yearlings released each year from Entiat NFH.

5. The USFWS shall apply a CWT to a representative proportion of the total number of marked spring chinook salmon yearlings released into the Entiat River each year.

6. The USFWS shall coordinate with co-managers to develop operational practices that provide for the effective removal and beneficial use of Carson NFH-lineage spring chinook adult returns to the hatchery that are surplus to egg take needs. Beneficial uses of surplus spring chinook salmon may include their use for the Omak Creek spring chinook salmon reintroduction program, distribution for tribal ceremonial and subsistence use, and distribution to food banks.

7. The USFWS shall maintain the Entiat NFH ladder and trapping facility open through the entire duration of the annual Carson-lineage spring chinook salmon adult return period to maximize removal of the fish from critical habitat for listed spring chinook salmon.

8. The USFWS, as lead agency, and in co-ordination with the co-managers, should collect a representative number of samples from Entiat NFH-origin and Entiat River natural-origin juvenile and adult spring chinook salmon populations each through at least 2005 for genetic stock identification analysis.

6.4.1.3 Winthrop NFH Spring Chinook Program

1. The USFWS shall limit, as an annual management intent, the production of spring chinook salmon smolts at Winthrop NFH to 600,000 yearlings, for release in April or May.

2. The USFWS shall discontinue releases of Carson stock spring chinook salmon smolts and prioritize the use of listed Methow River basin spring chinook stocks to sustain the Winthrop NFH program.

3. The USFWS shall coordinate with NMFS and the fishery co-managers to develop an assessment of needed Methow "Composite" stock release numbers from hatcheries in the Methow River basin.

4. The USFWS shall internally tag 100 percent of the spring chinook salmon yearlings released each year from Winthrop NFH. This mark will allow for the differentiation of stocks returning to the region for spawning and stock assessment purposes.

5. The USFWS shall coordinate with NMFS and other co-managers regarding any spring chinook salmon trapping protocols developed and applied at Winthrop NFH, and the appropriate disposition of any spring chinook salmon adults returning to the hatchery.

6. The USFWS shall coordinate with co-managers to develop operational practices that provide for the effective removal and beneficial use of Carson NFH-lineage spring chinook adult returns to the basin. Beneficial uses of surplus spring chinook salmon may include their use for the Omak Creek spring chinook salmon reintroduction program, distribution for tribal ceremonial and subsistence use, and distribution to food banks.

7. The USFWS shall limit the number of Carson-lineage spring chinook salmon pre-smolts or smolts transferred each year from Leavenworth Complex hatcheries for acclimation and release in Omak Creek to 300,000. The limit defines a maximum yearling release level for 2001-2005.

8. The USFWS shall limit the number of Carson-lineage spring chinook salmon adults transferred each year from Leavenworth Complex hatcheries for release into Omak Creek to 50 pairs (100 fish).

9. The USFWS shall ensure that 100 percent of the adult spring chinook salmon transferred for release into Omak Creek during the experimental reintroduction period are externally marked. An external mark is necessary to differentiate direct hatchery adult releases from spring chinook returning to Omak Creek as a result of natural production, or releases of juvenile artificially propagated fish.

10. The USFWS shall limit the number of Carson-lineage spring chinook salmon eyed eggs or fry transferred each year from Leavenworth Complex hatcheries for release into Omak Creek to 100,000. Eyed eggs or fry may only be transferred to Omak Creek as a

substitute for adult spring chinook salmon releases. Therefore, no eyed egg or fry transfers are allowed if adult fish of the same brood year have been out-planted. The limit defines a maximum eyed egg or fry release level, as a substitute for adult releases, for 2001-2004. Consideration of continued release are subject to results of these initial year releases and development of a HGMP by the Colville Tribes.

11. The USFWS shall apply an externally visible mark to 100 percent of the spring chinook fry, pre-smolts and smolts transferred each year to Omak Creek. A representative proportion of the marked pre-smolts and smolts shall also receive a CWT for fisheries and escapement contribution and overall survival evaluation purposes.

12. The USFWS, NMFS and the Colville Tribes shall review the use of Carson stock spring chinook salmon for reintroduction into the Okanogan River basin, and develop a proposed long term plan identifying the preferred spring chinook stock for reintroduction. This review and plan development process will be conducted in year 3 (2004) or 4 (2005) of the reintroduction effort. The feasibility of retaining the donor Carson stock, supplanting the Carson stock with "local" listed Methow "Composite" stock (when available), or of using some other appropriate spring chinook salmon stock, shall be considered. The need for this review process recognizes that the Omak Creek spring chinook reintroduction program is experimental. The most appropriate, most successful means for creating a viable, self-sustaining natural-origin spring chinook return to the basin should be evaluated and identified.

6.4.2 Bonneville Power Administration/Yakama Nation

1. The BPA/Yakama Nation shall, as the management intent, limit juvenile fish releases to 1,000,000 coho salmon smolts in the Wenatchee River basin and 250,000 coho salmon smolts in the Methow River basin annually for the feasibility study portion of the reintroduction effort. The number of juvenile coho salmon released into subbasin areas may be increased following Coho Technical Committee and NMFS Salmon Recovery Division approval.

2. The duration of acclimation at each of the release locations shall be no less than three weeks to adequately foster fidelity of returning adult fish to the release location, and to reduce the risk of homing back to the hatcheries from which the fish were transferred as pre-smolts.

3. Juveniles that are progeny of adult coho salmon returning to the Wenatchee River shall, as a priority, be released into the Wenatchee basin. The specific release locations and number will be determined in the Coho Technical Workgroup forum and must be approved by NMFS Salmon Recovery Division.

4. Juveniles that are progeny of adult coho salmon returning to the Methow River shall, as a priority, be released into the Methow River basin. The specific release locations and number will be determined in the Coho Technical Workgroup forum and must be approved by NMFS Salmon Recovery Division.

5. Approval of new acclimation and release sites beyond those currently identified in the HGMP shall be obtained from NMFS Salmon Recovery Division prior to being utilized.

6. The BPA/Yakama Nation shall allow free, unimpeded passage of listed steelhead through the old Icicle Creek channel during the time period that the channel is used to acclimate coho salmon smolts. If listed steelhead passage is determined to be impeded (either upstream or downstream) the BPA/Yakama Nation must correct the situation immediately.

7. The BPA/Yakama Nation shall continue to work with the USFWS, Icicle Creek Watershed Council and Washington Trout on agreements to use the old Icicle Channel for acclimation of coho smolts.

8. The BPA/Yakama Nation shall identify, for NMFS approval, adult coho salmon spawning and holding facilities that will be used to maintain returning adults for the production of coho salmon in the Wenatchee River basin.

9. To minimize incidental injury and mortality levels to listed populations present in Nason Creek, BPA/Yakama Nation shall limit the annual number of spring chinook and steelhead juveniles that may be captured, handled, and released in the Nason Creek coho predation study to not exceed 1,000 and 500, respectively. Incidental lethal takes associated with the study shall not exceed 20 spring chinook and 10 steelhead juveniles.

10. The PBA/Yakama Nation shall comply with NMFS electro-fishing guidelines when the equipment is used to collect fish. Incidental take in the form of capture, handling and release associated with electro-fishing shall of spring chinook salmon and steelhead juveniles shall not exceed 300 and 300, respectively. Incidental lethal takes associated with electro-fishing shall not exceed 30 spring chinook and 30 steelhead juveniles.

11. The BPA/Yakama Nation shall report tow net capture results by species in annual reports, including fish numbers, life stage, and condition upon release.

12. Only tow nets fitted with cod-end buckets shall be used to capture fish for the proposed sockeye/coho interaction study in Lake Wenatchee. In the event that the bongo-type tow nets proposed for sampling transect areas in Lake Wenatchee prove ineffective in capturing fish, The BPA/Yakama Nation shall contact the Salmon Recovery Division of NMFS to propose alternative sampling gear types and methods. Alternative sampling gear and methods must ensure safe capture of listed fish that may be encountered, posing minimal risk of injury and mortality.

13. The BPA/Yakama Nation shall apply internal tags (CWT or PIT) in all coho salmon smolts to be released into the Wenatchee River and Methow River basins each year. During the development of the local UCR coho stock, external marking or tagging shall not be required.

14. The BPA/Yakama Nation shall conduct spawning ground carcass surveys to determine the number of coho salmon on the spawning grounds and the location of spawning. The results shall be summarized and submitted to NMFS in an annual report.

15. The BPA/Yakama Nation shall submit annual broodstock management protocols to NMFS for approval by June 30 of the collection year. The protocols should be coordinated with other fish resource managers and shall include run forecast estimates, broodstock collection goals, and spawning ground escapement targets.

16. The Yakama Nation shall limit the number of adult coho salmon on the Nason Creek spawning grounds to 459, which is ½ the estimated spring chinook salmon carrying capacity (expressed as 917 spawners), or no greater than the total number of spring chinook salmon adults estimated inseason that have escaped to Nason Creek that year, whichever is smaller. This condition may be revised based on new information and agreement by the Coho Hatchery Work Group and NMFS Salmon Recovery Division.

17. The Yakama Nation, in cooperation with the Douglas PUD and the WDFW, may operate the Wells Dam east ladder trap no more than three days per week between September 1 and December 7 for the collection of coho salmon broodstock when steelhead are present. When operating, active trapping may occur up to 16 hours per day. If both the east and west ladders are operated, they must be operated on the same three days during the week. The ladder shall be open at night to allow passage for listed steelhead. If WDFW is operating the east ladder trap for broodstock collection, any coho incidentally caught may be kept for broodstock or radio-tagged. All steelhead diverted into the trapping facility will count toward the take limit unless other wise authorized under separate ESA permit or ITS (i.e., steelhead captured during WDFW's steelhead broodstock collection will not apply toward the Yakama Nation's incidental steelhead take). If WDFW is not operating the east ladder trap then incidental take in the form of diversion into the trap, capture, handle, and release shall not exceed 4.5 percent of the total adult steelhead to return over Wells Dam.

18. The Yakama Nation, in cooperation with the Douglas PUD and the WDFW, may operate the Wells Dam west ladder trap no more than three days per week between September 1 and December 7 for the collection of coho salmon broodstock when steelhead are present. When operating, active trapping may occur up to 16 hours per day. If both the east and west ladders are operated, they must be operated on the same three days during the week. The ladder shall be open at night to allow passage for listed steelhead. All steelhead diverted into the trapping facility will count toward the take limit unless otherwise authorized under separate ESA permit or ITS (i.e., steelhead captured during WDFW's steelhead broodstock collection will not apply toward the Yakama Nation's incidental take). If WDFW is operating the west ladder trap for broodstock collection, any coho incidentally caught may be kept for broodstock or radio-tagged. All steelhead handled during WDFW's steelhead broodstock collection will not apply towards the Yakama Nation's incidental steelhead take. Should steelhead broodstock collection goals be met early, or if WDFW is not operating the west ladder trap then incidental take in the form of diversion into the trap, capture, handle, and release shall not exceed 4.5 percent of the total adult steelhead to return over Wells Dam.

19. The Yakama Nation, in coordination with the WDFW and Chelan PUD, may operate the Tumwater Dam trap between September 1 and December 7 for the collection of coho salmon broodstock or radio-tagging no more than three days per week when steelhead are present. When operating, trapping may occur up to 16 hours per day. The ladder shall be open at night to allow passage for listed steelhead. All steelhead diverted into the trapping facility will count toward the take limit unless other wise authorized under separate ESA permit or ITS. Incidental take in the form of capture, handle, and release shall not exceed 3.5 percent of the total number of adult steelhead to return to the Wenatchee River as measured by the difference in steelhead count at Rock Island and Rocky Reach Dams. If increased coho collection at the Tumwater Dam trap is necessary to limit the number of coho adults on the spawning grounds in Nason Creek in

accordance with Condition 16 above, then this incidental take limit may be exceeded per ongoing consultation with NMFS Salmon Recovery Division.

20. The Yakama Nation, in coordination with the WDFW and Chelan PUD, may operate the Dryden Dam trap for the collection of coho salmon broodstock no more than five days per week between September 1 and December 7 when steelhead are present. When operating, trapping may occur up to 24 hours per day. All steelhead diverted into the trapping facility will count toward the take limit unless other wise authorized under separate ESA permit or ITS (i.e., steelhead captured during WDFW's steelhead broodstock collection under permit 1395). If steelhead broodstock collection goals are met early and/or WDFW is not operating the Dryden Dam traps, then incidental take in the form of capture, handle, and release shall not exceed 5 percent of the total adult steelhead to return to the Wenatchee River as measured by the difference in steelhead count at Rock Island and Rocky Reach Dams.

21. The Yakama Nation, in coordination with the USFWS, may operate fish traps at Dam 5 in Icicle Creek and/or the LNFH fishway between September 1 and December 7 for the collection of coho salmon broodstock. When operating, trapping may occur up to 24 hours per day, 7 days per week. Incidental take of steelhead in the form of capture handle, and release shall not exceed 0.5 percent of the total adult steelhead to return to the Wenatchee River as measured by the difference in steelhead count at Rock Island and Rocky Reach Dams.

22. The Yakama Nation, in coordination with the WDFW and Grant PUD, may operate the Priest Rapids Dam trap for the collection of coho broodstock and for inserting radio tags no more than two days per week between August 20 and November 20 when steelhead are present, in a manner consistent with the WDFW trap operation schedule and procedures. When operating, active trapping may occur up to 16 hours per day. The ladder shall be open to passage at night to allow passage for listed steelhead. If WDFW is operating the Priest Rapids Dam trap for steelhead stock assessment and/or radio tagging steelhead handled will not apply toward the Yakama Nation's incidental take limit. Between October 15 and November 20, when WDFW is not operating the Priest Rapids Dam trap for steelhead stock indexing, incidental take in the form of capture, handle, and release shall not exceed 3.5 percent of the total adult steelhead to return over Priest Rapids Dam.

6.4.3 National Marine Fisheries Service

In issuing permit 1347 authorizing incidental takes of listed spring chinook salmon and steelhead, NMFS shall require the permit holders to adhere to the activities as proposed and the terms and conditions identified in Section 2 of this Opinion.

7 REINITIATION OF CONSULTATION

This concludes formal consultation of the actions outlined in the applications for section 10(a)(1)(A) permits. As provided in 50 CFR §402.16, reinitiation of formal consultation is required if: (1) the amount or extent of annual take, either intentional take or incidental take, is exceeded or is expected to be exceeded; (2) new information reveals effects of the agency action that may affect listed species in a way not previously considered; (3) the action is modified in a way that causes an effect to listed species that was not previously considered; or (4) a new

species is listed or critical habitat is designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, the operation that results in exceeding take must cease, and consultation must be reinitiated.

Specifically, if new monitoring or research information indicate that adverse genetic impacts are occurring on UCR spring chinook salmon from operation of the proposed unlisted chinook salmon programs, then consultation must be reinitiated.

8 MAGNUSON-STEVENS ACT ESSENTIAL FISH HABITAT CONSULTATION

"Essential fish habitat" (EFH) is defined in section 3 of the Magnuson-Stevens Act (MSA) as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." NMFS interprets EFH to include aquatic areas and their associated physical, chemical and biological properties used by fish that are necessary to support a sustainable fishery and the contribution of the managed species to a healthy ecosystem.

The MSA and its implementing regulations at 50 CFR 600.920 require a federal agency to consult with NMFS before it authorizes, funds or carries out any action that may adversely effect EFH. The purpose of consultation is to develop a conservation recommendation(s) that addresses all reasonably foreseeable adverse effects on EFH. Further, the action agency must provide a detailed, written response to NMFS within 30 days after receiving an EFH conservation recommendation. The response must include measures proposed by the agency to avoid, minimize, mitigate, or offset the impact of the activity on EFH. If the response is inconsistent with NMFS ' conservation recommendation, the agency must explain its reasons for not following the recommendations.

Thus, one of the objectives of this consultation is to determine whether the proposed actions of artificially propagated programs in the UCR region of Washington State - are likely to adversely affect EFH. If the proposed actions are likely to adversely affect EFH, conservation recommendations will be provided.

8.1 Identification of Essential Fish Habitat

The Pacific Fishery Management Council (PFMC) is one of eight Regional Fishery Management Councils established under the Magnuson-Stevens Act. The PFMC develops and carries out fisheries management plans for Pacific coast groundfish, coastal pelagic species, and salmon off the coasts of Washington, Oregon and California. Pursuant to the MSA, the PFMC has designated freshwater and marine EFH for chinook and coho salmon (PFMC 1999). For purposes of this consultation, freshwater EFH for salmon in Washington includes all streams, lakes, ponds, wetlands, and other water bodies currently or historically accessible to Pacific salmon, except upstream of the impassable dams. In the future, should subsequent analyses determine the habitat above any impassable dam is necessary for salmon conservation, the PFMC will modify the identification of Pacific salmon EFH (PFMC 1999). Marine EFH for Pacific salmon in Oregon and Washington includes all estuarine, nearshore and marine waters within the western boundary of the U.S. Exclusive Economic Zone (EEZ), 200 miles offshore.

8.2 Proposed Action and Action Area

For this EFH consultation, the proposed actions and action area are as described in detail above. The actions are the operation of artificially propagated programs that collect, rear and release unlisted salmon within the geographical boundaries of the UCR Spring-Run Chinook Salmon ESU and the UCR Steelhead ESU, and their effects on the survival and recovery of listed spring chinook salmon and steelhead. The proposed action area includes freshwater areas accessible to anadromous salmon upstream of the Yakama River's confluence with the mainstem Columbia River, excluding waters upstream of Chief Joseph Dam. A more detailed description and identification of EFH for salmon is found in Appendix A to Amendment 14 to the Pacific Coast Salmon Plan (PFMC 1999). Assessment of the impacts on these species' EFH from the above proposed action is based on this information.

8.3 Effects of Proposed Action

Based on information submitted by the action agencies, as well as NMFS ' analysis in the ESA consultation above, NMFS believes that the effects of the actions on EFH are likely to be within the range of effects considered in the ESA portion of this consultation.

8.4 Conclusion

Using the best scientific information available and based on its ESA consultation above, as well as the foregoing EFH sections, NMFS has determined that the proposed actions are likely to adversely affect EFH for Pacific salmon.

8.5 Essential Fish Habitat Conservation Recommendations

The Reasonable and Prudent Measures and the Terms and Conditions outlined above are applicable to designated salmon EFH. Therefore, NMFS recommends that those same Reasonable and Prudent Measures, and the Terms and Conditions be adopted as the EFH Conservation Recommendation for this consultation.

8.6 Statutory Response Requirement

Section 305(b)(4)(B) of the MSA and implementing regulations at 50 CFR section 600.920 require a federal action agency to provide a detailed, written response to NMFS within 30 days after receiving an EFH conservation recommendation. The response must include a description of measures proposed by the agency to avoid, minimize, mitigate or offset the impact of the activity on EFH. If the response is inconsistent with a conservation recommendation from NMFS , the agency must explain its reasons for not following the recommendation.

8.7 Consultation Renewal

The action agencies must reinitiate EFH consultation if plans for these actions are substantially revised in a way that may adversely affect EFH, or if new information becomes available that affects the basis for the EFH conservation recommendations (50 CFR Section 600.920(k)).

9 REFERENCES

Section 7(a)(2) of the ESA requires biological opinions to be based on "the best scientific and commercial data available." This section identifies the information sources in developing this Opinion.

1.0 INTRODUCTION

1.1 Background

NOAA Fisheries proposes to issue incidental take permit 1347 pursuant to section 10(a)(1)(B) of the Endangered Species Act (ESA). The permit would authorize take of listed chinook salmon and steelhead incidental to operation of artificial propagation programs rearing and releasing unlisted species. Under section 10(a)(1)(B), non-federal entities may apply for permits from NOAA Fisheries to incidentally take ESA-listed species under the jurisdiction of NOAA Fisheries if such taking is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Section 10(a)(2)(A) defines the requirement for a complete application. Following public comment, a permit shall be issued if the applicant provides a complete conservation plan pursuant to ESA section 10(a)(2)(B) that specifies: (1) the taking will be incidental; (2) the applicant will, to the maximum extent practicable, monitor, minimize, and mitigate the impacts of such taking; (3) the applicant will ensure that adequate funding for the conservation plan will be provided; (4) the taking will not appreciably reduce the likelihood of the survival and recovery of the species in the wild; and (5) any other measures that the Secretary may require as being necessary or appropriate will be met.

On December 15, 1999, the WDFW submitted an application in the form of a Conservation Plan (WDFW 1999a) to NOAA Fisheries for an ESA section 10(a)(1)(B) permit for the incidental take of ESA-listed anadromous fish species that may result from operation of artificial propagation programs of unlisted salmon at hatcheries in the UCR region; the application was made available for public comment for 30 days, closing on November 15, 2001. Included with the WDFW permit application were three Hatchery and Genetic Management Plans (HGMPs), which supplemented the Conservation Plan by providing in-depth descriptions of each artificial propagation program, and measures applied to minimize risks of adverse effects on natural fish populations (WDFW 1999b; 1999c; 1999d).

Negotiations were completed on three Habitat Conservation Plans (HCPs) in April 2002; two with Chelan PUD for the operation of Rock Island Dam and Rocky Reach Dam (CPUD 2002a; 2002b), and one with Douglas PUD for the operation of Wells Dam (DPUD 2002). A public comment period closed on the HCPs on July 25, 2002. The HCPs provide for implementation of the artificial propagation programs addressed in this EA, required as mitigation for hydro project operation by the Federal Energy Regulatory Commission (FERC). The HCPs specifically obligate NOAA Fisheries to issue pertinent section 10 permits to the PUDs for operation of the artificial propagation programs they implement.

The proposed permit (1347) would be a mechanism by which NOAA Fisheries can ensure that the PUDs are adequately funding the programs in a manner that minimized any adverse impacts the non ESA-listed artificial propagation programs could have on the protected stocks. It also would help ensure that the programs are operated by WDFW in an effective manner to meet specific program objectives as determined by the agencies responsible for managing the natural fish resources.

Therefore, the proposed section 10(a)(1)(B) permit would be issued jointly to the WDFW, Chelan PUD, and Douglas PUD. Table 1 lists the proposed artificial propagation programs.

Table 1. List of WDFW operated unlisted salmon artificial propagation programs considered in this EA (FH=Fish Hatchery).

Program	Primary Facilities	River
Wenatchee Sockeye	Lake Wenatchee Net Pens, Eastbank FH	Wenatchee
Wenatchee Summer Chinook	Eastbank FH, Dryden Pond	Wenatchee
Methow Summer Chinook	Eastbank FH, Carlton Pond	Methow
Okanogan Summer Chinook	Eastbank FH, Similkameen Pond	Okanogan
Wells Summer Chinook	Wells FH	Columbia River Mainstem
Turtle Rock Summer Chinook	Turtle Rock FH	Columbia River Mainstem
Priest Rapids Fall Chinook	Priest Rapids FH	Columbia River Mainstem

1.2 Description of the Proposed Action

The artificial propagation programs are described in the ESA section 10 incidental take permit application and HGMPs submitted to NOAA Fisheries by the WDFW (WDFW 1999a;1999b; 1999c; 1999d) and summarized below (section 2.3.1). The rationale for, and obligation to implement, these propagation programs is described in the three HCPs (CPUD 2002a; 2002b; DPUD 2002) and summarized here.

The hatcheries produce unlisted summer chinook, fall chinook (*O. tshawytscha*), and sockeye (*O. nerka*) salmon to mitigate for the loss of natural fish production due to hydroelectric project operation in the Columbia River. The operation of these artificial propagation programs would provide unlisted salmon adults to augment harvests in treaty reserved Columbia River tribal fisheries in the Columbia River, and non-Indian fishery harvests in the Columbia River and in Pacific Northwest marine fishing areas. The adult salmon produced by the programs are also intended to supplement naturally spawning populations in the UCR region, helping to preserve those populations commensurate with the operation of hydropower projects impacting salmon survival. The salmon produced for harvest purposes provide economic opportunity and cultural benefits to Columbia River treaty tribes, and economic benefits for local communities through the sale of fish, licences, equipment, and the conduct of other financial transactions related to recreational and commercial fisheries.

1.3 Purpose Of and Need For the Proposed Action

The purpose of and need for the issuance of the section 10(a)(1)(B) permit 1347 is to ensure that the activities covered under the permit have been thoroughly analyzed for adverse impacts to listed species, and are in compliance with the ESA, and to ensure the continuation of the programs and

their implementation. The purpose of this EA is to evaluate the potential environmental effects as a consequence of NOAA Fisheries issuing a permit jointly to the WDFW, Chelan PUD, and Douglas PUD and implementing a conservation plan for the incidental take of ESA-listed anadromous fish associated with the proposed artificial propagation programs.

1.4 Scope of the Action

The scope of the action considered here addresses artificial propagation actions proposed by the WDFW, Chelan PUD, and Douglas PUD in the upper Columbia River region for the ten year period from 2003 to 2013. These actions include collecting adult unlisted summer chinook, fall chinook, and sockeye salmon adults for broodstock through trapping in UCR tributaries or at the hatcheries, propagating resultant progeny in the hatchery environment, releasing juvenile salmon from the hatcheries or from satellite facilities into the natural environment, and conducting scientific research and monitoring activities associated with the hatchery operations. This EA does not address the entire scope of the HCPs. A separate Environmental Impact Statement has been completed (NOAA Fisheries 2002) and has undergone a public comment period which ended in May 2001 (65 FR 82976) . The activities that would occur under the proposed actions considered here are expected to incidentally affect endangered UCR spring chinook salmon and steelhead as a result of broodstock trapping, hatchery facility water withdrawal and effluent discharge practices, and release of juvenile fish. Threatened bull trout (*Salvelinus confluentus*) of the Columbia River distinct population segment may also be affected by the hatchery activities.

1.5 Action Area

The key issues identified during the development of the application and HGMPs for a section 10 permit focused on the effects of the proposed programs on listed endangered spring chinook salmon and steelhead in the UCR ESUs (Figures 1 and 2). The WDFW concluded that the benefits of allowing the programs to occur outweighed the small incidental impacts on listed species.

This EA's action area includes all habitat accessible to anadromous salmon from the vicinity of Priest Rapids Dam on the mainstem Columbia River upstream to the border with Canada, including the mainstem Columbia River, the Wenatchee, Methow, and Okanogan Rivers, and their tributaries. The locations of the WDFW hatchery facilities considered in this EA within this action area are indicated in Figure 3.

2.0 ALTERNATIVES INCLUDING THE PROPOSED ACTION

Three alternatives were identified and considered in this EA: Alternative one (no action) is to not issue an incidental take permit for the artificial propagation activities specified in the permit application, HGMPs, and HCPs; Alternative two is to issue an incidental take permit based on the application, HGMPs, and HCPs without any additional specific conditions; and Alternative three (proposed action) is to issue an incidental take permit jointly to the WDFW, Chelan PUD, and Douglas PUD based on the application, HGMPs, and the HCPs, with additional specific conditions to minimize adverse impacts on the ESA listed salmonids and to enhance conservation efforts. The major aspects of the identified alternatives are described below.

2.1 Alternative One - Do Not Issue Permit (No Action)

Under a No Action alternative, NOAA Fisheries would not issue an ESA section 10(a)(1)(B) permit authorizing incidental takes of ESA-listed species associated with the activities proposed in the Application, HGMPs, and HCPs. The Conservation Plan, HGMPs, and HCPs, would not be implemented.

This alternative would effectively prohibit the incidental take of ESA-listed fish associated with the operation of the unlisted salmon hatchery operations. This alternative would therefore prohibit critical aspects of the artificial propagation programs, including broodstock trapping and juvenile fish releases in the proposed action area, because to do so the WDFW, Chelan PUD, and Douglas PUD would likely be in violation of the ESA. Limitations on application of the take prohibitions under section 4(d) are not available because the UCR spring chinook and UCR steelhead ESUs are listed as Endangered. The Chelan PUD and Douglas PUD would not be able to meet the HCP requirements of implementing artificial propagation programs to compensate for fish losses due to hydro project operations, and would not be able to obtain FERC licenses for operation of Rocky Reach Dam, Rock Island Dam and Wells Dam. To provide the broadest range of effects for the purpose of this analysis, NOAA Fisheries assumes that the programs would be discontinued if the permit was not issued.

2.2 Alternative Two - Issue Permit Without Conditions

Under this alternative, a permit would be issued to the applicant based strictly on the application, HGMPs, and pertinent terms of the HCPs, without additional special conditions to minimize adverse effects on listed salmon and steelhead. The Application, HGMPs, and HCPs include protocols for broodstock collection, artificial propagation, release of unlisted salmon species and mitigation requirements of hydro project operation impacts required in FERC licenses. While permit conditions that might otherwise be imposed would likely encompass and resemble the protocols described in the application, no requirement that the WDFW, Chelan PUD, and Douglas PUD follow those specific implementation and reporting tasks would be imposed under this alternative. With the exception that special conditions would not be imposed by NOAA Fisheries, the description of this alternative mirrors the description of the proposed action (section 2.3, below). The disadvantage of this alternative is that the WDFW, Chelan PUD, and Douglas PUD would not

be required to follow the specific implementation and reporting tasks that would be imposed under Alternative 3. The artificial propagation programs could be altered to increase incidental take of protected UCR spring chinook and UCR steelhead, thereby increasing the likelihood of significant impacts on the protected stocks.

2.3 Alternative Three - Issue Permit With Conditions (Proposed Action)

The proposed action alternative is to issue a permit under section 10(a)(1)(B) of the ESA based on the Application, HGMPs, and HCPs as modified by additional special conditions that NOAA Fisheries may require as being necessary and appropriate. NOAA Fisheries' special conditions would further minimize the risk of annual take of ESA-listed anadromous fish that may occur through the proposed actions. NOAA Fisheries' special conditions would also help to ensure that the annual take would not jeopardize the continued existence of ESA-listed anadromous salmon and steelhead. Issuance of the permit would meet FERC license requirements pertaining to the mitigation for operation of Rocky Reach Dam, Rock Island Dam, and Wells Dam. The permit would expire on December 31, 2013.

2.3.1 Proposed Artificial Propagation Programs

Below are descriptions of unlisted salmon artificial propagation programs proposed by the WDFW in the action area. This information is summarized from the WDFW Conservation Plan (WDFW 1999a), and from three HGMPs (WDFW 1999b; 1999c; 1999d), and HCPs (CPUD 2002a; 2002b; DPUD 2002) submitted to NOAA Fisheries and that would be addressed in the proposed permit.

Specific activities needed to implement the artificial propagation programs may be altered and modifications to program implementation may be made through the Hatchery Committees as described in the HCPs (CPUD 2002a; 2002b; DPUD 002). The Hatchery Committees consist of one representative of each signatory entity for each of the HCPs. NOAA Fisheries will be represented in the Hatchery Committee forum to ensure activities proposed by the Hatchery Committees are consistent with ESA recovery goals and do not operate to the detriment of protected species. The minor adjustments that may be made by the Hatchery Committees are not expected to alter the effects on the human environment.

Eastbank FH Programs

The Eastbank FH began operation in 1989 to mitigate for salmon smolt losses resulting from the operation of Rock Island Dam. The facility is located on the east side of the Columbia River near Rocky Reach Dam at river mile 474, seven miles north of Wenatchee, Washington. The hatchery complex would operate with five satellite facilities, located on five different waters in the action area: Dryden Pond on the Wenatchee River, Chiwawa Pond on the Chiwawa River, Lake Wenatchee Net Pens on Lake Wenatchee, Carlton Pond on the Methow River, and Similkameen Pond on the Similkameen River. The hatchery would be used for incubation and rearing of steelhead, and spring chinook, summer chinook, and sockeye salmon. There would be no on-station releases of fish at Eastbank FH.

Broodstock would be not collected at Eastbank FH. Sockeye and summer chinook salmon propagated at the hatchery originate from broodstock collected in the Wenatchee River (Dryden and Tumwater Dams) and at Wells Dam as described below for each program.

Transfers of fish reared at Eastbank FH to other locations would occur as described below, for the watershed areas where the fish would be released. Production goals for Eastbank FH would be: 864,000 summer chinook for acclimation and release into the Wenatchee River; 200,000 Wenatchee sockeye salmon for acclimation and release into Lake Wenatchee; 400,000 summer chinook for acclimation and release into the Methow River; and 576,000 summer chinook for acclimation and release into the Okanogan River Basin.

Wenatchee Sockeye Salmon Program

The program's purpose is to mitigate for the loss of sockeye salmon attributable to the construction and operation of Rock Island Dam (WDFW 1999d). The program is funded by the Chelan PUD. The Wenatchee sockeye salmon program uses indigenous Wenatchee River Basin sockeye salmon stock returning to the Little Wenatchee and White Rivers as broodstock. Broodstock collection occurs at Tumwater Dam during the annual migration of sockeye adults returning to the Lake Wenatchee Basin generally from mid-July through early August. Specific broodstock collection protocols are developed annually based on run size estimates and river environment conditions. The broodstock collection goal is approximately 260 adults or no more than 10% of the total run.

Sockeye broodstock are transported to the Lake Wenatchee Net Pens for holding through spawning. Eggs and juvenile sockeye salmon are incubated and early reared at the WDFW's Eastbank Fish Hatchery (FH), which is located on the mainstem Columbia River at river mile 474 near Rocky Reach Dam. After four to six months of rearing, the sockeye would be liberated during September, October or November from the net pens into Lake Wenatchee. The hatchery sockeye fingerlings overwinter in the lake, and emigrate to the ocean the following spring as yearling smolts. All Lake Wenatchee Net Pen origin sockeye would be identifiable from natural sockeye salmon by an adipose fin clip and coded wire tag (CWT). The annual production goal for the Wenatchee sockeye salmon program is 200,000 fish.

Wenatchee Summer Chinook Salmon Program - Dryden Pond

The purpose of this summer chinook salmon artificial propagation program in the Wenatchee River Basin is to mitigate for the loss of fish due operation of Rocky Reach and Rock Island Dams. The WDFW's Eastbank FH, located on the mainstem Columbia River, is used for spawning, incubation and early rearing. Pre-smolt summer chinook salmon produced at Eastbank FH would be transferred to acclimation sites in the Wenatchee Basin (primarily Dryden Pond) for acclimation and release.

Broodstock used in the Wenatchee summer chinook salmon artificial propagation program would be taken from native fish returning to the Wenatchee River and its tributaries. The annual broodstock collection goal for the program would be about 492 adults, but an annual broodstock collection protocol would be developed based on run size estimates, run timing, and river environment conditions. Proposed broodstock collection facilities include traps at Dryden (river

mile 16) and Tumwater Dams (river mile 32) on the Wenatchee River and trapping would occur primarily during July and August, but may extend through November in some years for late-arriving summer chinook salmon (WDFW 1999a; NMFS 2001).

Summer chinook salmon collected at the Dryden and Tumwater Dam traps would be transported to Eastbank FH for holding through spawning. The progeny of these broodstock would be reared at Eastbank FH to the pre-smolt stage. Summer chinook salmon would be transferred from Eastbank FH to acclimation sites in the Wenatchee Basin (usually Dryden Pond) for acclimation and release. The fish would be released as migration-ready yearlings at a size of 10 to 12 fish per pound (~6-6.5 inches fork length) in late April or early May. All summer chinook salmon yearlings released in the Wenatchee Basin would be marked with an adipose fin clip and CWT combination for visual identification, and for monitoring and evaluation purposes. The annual production goal would be 864,000 yearling summer chinook salmon for release in the Wenatchee River Basin.

Methow Summer Chinook Salmon Program - Carlton Pond

The purpose of this summer-run chinook salmon artificial propagation program is to mitigate for the loss of summer chinook salmon adults that would have been produced in the Methow River Basin in the absence of the Wells, Rocky Reach, and Rock Island Dams.

Summer chinook salmon presently used in the Methow (Carlton Pond) program would be the progeny of natural or hatchery-origin fish originating from the Methow and Okanogan River watersheds collected at Wells Dam. The Eastbank FH would be used for spawning, incubation and early rearing. Summer chinook salmon juveniles produced at Eastbank FH would be transferred to Carlton Pond on the Methow River for acclimation and release. Carlton Pond is located adjacent to the Methow River at river mile 36 near Twisp, Washington.

Summer chinook salmon adults used for the Carlton Pond program would be trapped by the WDFW at Wells Dam between early July and late August, and held through maturity at the Eastbank FH (WDFW 1999b). The annual broodstock collection goal would be developed annually, and is usually about 556 fish for the Carlton Pond combined with the Similkameen Pond Program (see below), with equal numbers of each sex.

Summer chinook salmon destined for release from Carlton Pond into the Methow River would be incubated and reared to fingerling size at Eastbank FH. Juvenile fish reared at Eastbank FH would be transferred as pre-smolts in early spring to Carlton Pond for continued rearing, and a spring-time release. The annual summer chinook salmon production objective in the Methow River would be 400,000 yearlings at an average size of 10 fish per pound. All summer chinook salmon yearlings would be marked with an adipose fin clip and CWT combination for visual identification and monitoring and evaluation purposes.

Okanogan Summer Chinook Salmon Program - Similkameen Pond

The purpose of the Okanogan summer chinook salmon artificial propagation program is to mitigate for the loss of summer chinook salmon adults that would have been produced in the Okanogan River Basin in the absence of Wells, Rocky Reach, and Rock Island Dams. The Eastbank FH

would be used for spawning, incubation and early rearing. Summer chinook salmon juveniles produced at Eastbank FH would be transferred to acclimation sites in the upper Okanogan River watershed (primarily Similkameen Pond) for acclimation and release. Similkameen Pond is located adjacent to the Similkameen River (a tributary to the Okanogan River) near Oroville, Washington.

Summer chinook salmon presently used in this program would originate from natural or marked hatchery-origin fish collected at the Wells Dam concurrent with broodstock for the Carlton Pond Program described above.

Fish reared at Eastbank FH would be transferred as fingerlings in the fall for overwintering at Similkameen Pond or other acclimation sites in the Okanogan Basin. The fish would be reared to yearling smolt size through the winter for release in the spring to acclimate the chinook to the release site. The annual summer chinook production objective in the Okanogan River Basin would be 576,000 yearlings at an average size of 10 fish per pound. All yearlings released through the program would be marked with an adipose fin clip and CWT combination for visual identification and monitoring and evaluation purposes.

Priest Rapids Fall Chinook Salmon Program

The goal of the Priest Rapids "upriver bright" (URB) chinook salmon program is to mitigate for the loss of fall-run chinook salmon adults that would have been produced in the region in the absence of the Priest Rapids Project (Priest Rapids and Wanapum dams) and John Day Dam. The hatchery facility is located on the mainstem Columbia River at river mile 397. The original stock used at the present Priest Rapids FH location came from late-run URB chinook salmon trapped at Priest Rapids Dam.

Fall chinook salmon would be trapped for use as broodstock from early September through November at the Priest Rapids FH trap, downstream of Priest Rapids Dam. Fall chinook salmon would be collected from the salmon that volunteer into the trap from September through November. Broodstock would be collected across the entire run to ensure that the run timing for the population is maintained. The broodstock collection goal at Priest Rapids FH would usually not exceed 6,102 adults.

The annual production goal would be 6,700,000 fall chinook sub-yearlings for release in June (WDFW 1999c). Fingerlings would be acclimated on river water for release as sub-yearling smolts on-station. Approximately 4% of the total annual release (approximately 268,000 fish) would receive an adipose fin clip and CWT combination to assess brood year fishery contribution and survival rates.

Turtle Rock Summer Chinook Salmon Program

Turtle Rock FH is operated as a mitigation facility for fishery impacts caused by the construction and operation of Rocky Reach Dam. The hatchery is located adjacent to the Columbia River two miles upstream from Rocky Reach Dam at river mile 475 on the Columbia River. The facility includes the old Rocky Reach FH, located just downstream from Rocky Reach Dam and rearing

ponds on Turtle Rock Island located in the Rocky Reach Dam pool. The facility would be used for summer chinook salmon incubation and rearing and steelhead rearing.

Summer chinook salmon broodstock would not be collected at Turtle Rock FH. Broodstock would be provided through collection of summer chinook salmon volunteers to the Wells FH trap. Summer chinook salmon adults collected at Wells FH would be primarily hatchery origin fish with a few natural origin salmon.

The Wells FH volunteer trap would operate from early July through late August. Annual broodstock collection protocols would be developed based on run size estimates and run timing, and would generally be about 1,208 adults for the Wells and Turtle Rock programs (WDFW 1999a; 1999b). The summer chinook broodstock collection effort would be curtailed in late August to minimize inclusion of fall chinook salmon into the summer chinook gene pool. Eggs taken from spawners at Wells FH would be shipped to Turtle Rock FH and for incubation and rearing.

The annual hatchery production goals would generally be 200,000 yearling summer chinook and 1,600,000 sub-yearling summer chinook salmon for release from Turtle Rock FH (WDFW 1999b). Yearlings would be released in April and sub-yearlings would be released in June. All yearling summer chinook released from Turtle Rock FH would be marked with an adipose-clip and CWT combination for visual identification and monitoring and evaluation purposes. All "accelerated" (early release timing at a larger size) sub-yearlings would be marked, but only 200,000 "normal" release timing sub-yearlings would be marked as a survival index group. Summer chinook juveniles destined for release from Turtle Rock FH would be transferred to the island ponds in November for six months of acclimation (April release of yearlings), or in April-May for three months of acclimation (June-July release of sub-yearlings).

Wells Summer Chinook Salmon Program

Wells FH is located on the mainstem Columbia River at river mile 516 just below Wells Dam. The hatchery operates as a mitigation facility for salmon fishery impacts caused by Wells Dam. Summer chinook adults collected as broodstock for the Wells summer chinook program would be trapped at the hatchery volunteer trap concurrent with broodstock for the Turtle Rock Program described above.

The annual on-station release goals would generally be 320,000 summer chinook yearlings released in April and 484,000 accelerated sub-yearlings released in June (WDFW 1999b). Summer chinook salmon yearlings and sub-yearlings produced at Wells FH would be reared entirely at the hatchery. All summer chinook salmon released into the Columbia River at Wells FH would be adipose fin clipped and CWT for visual identification and monitoring and evaluation purposes.

2.3.2 Conservation Plan

The application and HGMPs comprise a comprehensive conservation plan designed to minimize and mitigate for the incidental take of listed steelhead and spring chinook resulting from the unlisted hatchery salmon produced by WDFW in the UCR region. Below are general and specific

aspects of the conservation plan that are designed to minimize and mitigate the effects of the incidental take on listed species for each artificial propagation program. As stated in the Scoping section, all of the key issues identified were related to the listed anadromous salmon species in the region.

General Conservation Measures:
The permit applicants propose to apply the following general measures to minimize effects of the unlisted salmon artificial propagation programs on listed salmon and steelhead:

1. the production and release of smolts through fish culture and release practices, fostering rapid seaward migration with minimal rearing or delay in the rivers;
2. acclimation to release sites of all salmon that are transferred from main production hatcheries to satellite production facilities to minimize straying;
3. adipose fin clip and CWT applied to all hatchery salmon populations to allow for adequate monitoring of migration, fisheries contribution, and survival;
4. continued monitoring and research to investigate the ecological effects of fish culture practices, and to identify salmonid migration timing and behavior;
5. compliance with IHOT (1995) guidelines regarding fish health, genetics, local ecological interactions, hatchery practices, and hatchery operations to maintain healthy hatchery and wild salmonid populations;
6. compliance with all the WDFW fish transfer and disease standards to minimize the risk of disease transference to wild fish;
7. consistent achievement of hatchery effluent and best management practice standards set forth in National Pollutant Discharge Elimination System (NPDES) permits to avoid adverse affects on wild fish and their habitat; and
8. adherence to the annual Basin-wide salmon production ceiling established by NOAA Fisheries (NMFS 1995) to address ecological carrying capacity concerns in the migration corridors, the estuary, and the marine ecosystem, and to minimize over-all density-dependent effects of hatchery production on listed species.

Specific Conservation Measures:
Wenatchee Sockeye Salmon Program and Wenatchee Summer Chinook Salmon Program
The trap used to collect sockeye and summer chinook salmon broodstock at Tumwater Dam would be operated to allow free upstream passage of listed spring chinook salmon and steelhead on the days when the trap is not operated, and during nighttime on the days when trapping occurs. Trap operation to collect sockeye salmon would begin after July 15 each year to allow unobstructed passage of the main portion of the earlier-migrating spring chinook salmon populations. Any listed spring chinook encountered after that date would be passed upstream with minimal delay. Collection of listed steelhead adults is authorized for a conservation artificial propagation program under section 10 permit 1094, issued by NOAA Fisheries to the WDFW on February 4, 1998 (NMFS 1998). Concurrent species broodstock collection protocols, promulgated annually, would be designed to minimize adverse adult trapping impacts on all species normally encountered.

Methow, Okanogan, Turtle Rock, and Wells Summer Chinook Programs
These programs share trapping operations at Wells Dam and Wells FH. All steelhead encountered that would not be retained as broodstock, as authorized by the WDFW's section 10 permit 1094, would move through the Wells Dam traps with no substantial handling or delay. Run timing of spring chinook and summer chinook are quite distinct. No other chinook populations are present in the project area during the July-August summer chinook broodstock collection period. The risk of adverse genetic effects on the population would be diminished by operating the adult collection between late June and late August to exclude spring-run and fall-run chinook from collections. Protected spring chinook which may be incidentally trapped would be distinguished from the recently arriving summer chinook by external coloration and body conformation. Unless needed for authorized recovery program broodstock, listed spring chinook thus identified would be passed upstream with minimal delay.

Adverse effects on the natural summer chinook population, and on listed fish that may be encountered incidentally during trapping, would be minimized through the following measures:

1. The Wells Dam ladder traps would be continuously monitored and operation limited to three days per week during the summer chinook migration (late June through late August). The east ladder trap would be actively manned during trapping and the west ladder trap would be passively operated and checked at least daily when operating, ensuring minimal holding times for fish captured.
2. The Wells FH trap does not use a fish weir to guide fish into the hatchery fish ladder. All fish returning to Wells FH recruit to the trap as volunteers. The trapping program would therefore not be a "run of the river" operation, and captures of other species besides summer chinook salmon that were produced at the hatchery are minimal.
3. To minimize migration delays to fish other than the targeted species, the fish sorting flume in the west ladder trap would be staffed at all times while the fishway is barricaded for the purpose of guiding fish into the trap. Attraction flows from the false weir would be maintained to encourage fish to use the sorting flume.
4. The traps would be operated in a manner to reduce retention time in the holding pools above the fishways accessing the trap.
5. Fish not required for broodstock would be returned into the fishway as they move through the sorting flumes to continue their upstream migration.

Priest Rapids Fall Chinook Salmon Program
Adverse effects on listed fish that may be encountered incidentally during trapping, would be minimized through the following measures:

1. The Priest Rapids FH trap would be monitored and fish removed at least 3 days per week during the hatchery fall chinook migration (September through November).
2. The hatchery trap is located in the hatchery outlet channel ½ mile upstream from its confluence with the Columbia River. A fish weir is not used to guide fish into the hatchery outlet. All fish returning to Priest Rapids FH recruit to the trap as volunteers. The trapping program would therefore not be a "run of the river" operation, and captures of other species besides fall chinook salmon that were produced at the hatchery would be minimal.

3. Other salmonids incidentally trapped would be returned into the outlet channel to continue their migration.

2.3.3 Special Conditions

NOAA Fisheries proposes to issue a section 10(a)(1)(B) permit jointly to the WDFW, Chelan PUD, and Douglas PUD with special conditions. NOAA Fisheries' conditions are designed to minimize ESA-listed fish takes incidental to: the collection and spawning of adult unlisted sockeye, summer chinook, and fall chinook salmon; releases of unlisted salmon juveniles in the respective stream of origin to supplement the naturally spawning populations in the UCR Basin; and the conduct of associated hatchery scientific research and monitoring activities. Of primary concern in the development of the conditions for the proposed permit is the necessity to take special measures to avoid adverse impacts from artificial propagation, including demographic, ecological, and genetic impacts on the ESA-listed species. In addition to compliance with all measures identified in the application, HGMPs, and the HCPs, the permit holders would comply with special conditions that would address the following.

1. *Wenatchee River Basin* - Wenatchee Summer Chinook and Wenatchee Sockeye Salmon Programs

   a. The annual production of Wenatchee summer chinook for release from Dryden Pond into the Wenatchee River shall be limited to 864,000 yearlings released in April or May. The annual production of sockeye salmon for release from the Lake Wenatchee Net Pens into Lake Wenatchee shall be limited to 200,000 yearlings released in September, October or November.

   b. Monitoring and reporting of the contribution of hatchery-origin summer chinook and sockeye salmon to the naturally spawning populations shall be conducted annually. This information shall be included in the annual report for the program specified below.

   c. To minimize incidental capture of listed spring chinook salmon and steelhead during summer chinook and sockeye salmon trapping at Dryden and Tumwater dams, the annual broodstock collection protocols based on run size estimates, average run timing, and river environment conditions shall be developed and submitted to NOAA Fisheries by April 15th of each collection year. Operation of broodstock traps shall be limited to the following general schedules:
      1. The Dryden Dam traps may be operated seven days per week between July and November. The traps shall be passively operated on the right and left banks, and all fish removed at least daily on days of operation.
      2. The Tumwater Dam trap shall be operated no more than three days per week between mid-July and November. The Tumwater Dam trap would be monitored and all fish removed daily. The trap shall be open to allow

unimpeded passage of salmon, including steelhead, upstream of the trap at night.

d. The retention of adult summer chinook salmon shall be limited to about 492 fish at Dryden Dam subject to minor adjustments as determined in annual broodstock collection protocols to minimize incidental take effects on listed fish. Of the total collection goal, up to 123 summer chinook salmon may be collected after August 15 at Tumwater Dam to augment summer chinook salmon retention at Dryden Dam, as necessary.

e. The retention of adult sockeye salmon shall be limited to 260 mixed-origin or not more than 10% of the total run, whichever is lower, of run-at-large fish at Tumwater Dam, to be collected after the peak of the sockeye run past Rock Island Dam.

f. The WDFW shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during summer chinook and sockeye salmon trapping. The WDFW shall carefully handle and immediately release upstream listed spring chinook salmon and steelhead adults that are not intended for use as broodstock in concurrently operated and previously authorized listed stock recovery programs. The number of listed salmon and steelhead encountered during summer chinook and sockeye salmon trapping, and their general condition at release, shall be included in the annual report for the program specified in section 6 below.

g. The WDFW shall adipose fin clip and CWT all hatchery summer chinook salmon yearlings and sockeye salmon juveniles released into the Wenatchee River Basin.

2. *Methow Summer Chinook Program* - Carlton Pond

a. The annual production of summer chinook salmon into the Methow River shall be limited to 400,000 yearlings released in April or May.

b. To minimize incidental capture of listed spring chinook and steelhead during trapping at Wells Dam, the operation of the east and west ladder traps shall be limited to no more than three days per week between July and August. If both the east and west ladders are utilized, they shall be operated concurrently, operating on the same three days each week. The ladders shall be opened to fish passage at night to allow free passage of listed steelhead.

c. The retention of broodstock for the Methow and Okanogan summer chinook salmon programs at the Wells Dam shall be limited to about 556 Methow/Okanogan river-origin summer chinook salmon subject to minor adjustment as determined through annual broodstock collection protocols to minimize incidental take effects on listed fish.

d. The WDFW shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during trapping. The WDFW shall carefully handle and immediately release upstream incidentally captured listed spring chinook salmon and steelhead adults that are not intended for use as broodstock in concurrently operated and previously authorized listed stock recovery programs. The number of listed salmon and steelhead encountered during trapping, and their general condition at release, shall be included in the annual report for the program specified in section 6.

e. All hatchery summer chinook salmon yearlings released into the Methow River Basin shall have adipose fin clips and CWTs.

3. *Okanogan Summer Chinook Program* - Similkameen Pond

a. The annual production of summer chinook for release into the Similkameen or Okanogan Rivers shall be limited to 576,000 yearlings released in April or May.

b. The retention of broodstock for the Similkameen Pond and Carlton Pond (Methow Basin) programs at the Wells Dam shall be limited to about 556 Methow/Okanogan River-origin summer chinook salmon subject to minor adjustment as determined in annual broodstock collection protocols to minimize incidental take effects on listed fish.

c. The WDFW shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during trapping. The WDFW shall carefully handle and immediately release upstream incidentally captured listed spring chinook salmon and steelhead adults that are not intended for use as broodstock in concurrently operated and previously authorized listed stock recovery programs. The number of listed salmon and steelhead encountered during trapping, and their general condition at release, shall be included in the annual report for the program specified in section 6.

d. All hatchery summer chinook salmon yearlings released into the Okanogan River Basin shall have adipose fin clips and CWTs.

4. *Mainstem Columbia River* - Wells and Turtle Rock Summer Chinook Salmon Programs

a. The annual production of summer chinook for on-station release from Wells Hatchery shall be limited to 320,000 yearlings released in April and 484,000 sub-yearlings released in June.

b. The annual production of summer chinook for on-station release from Turtle Rock Hatchery into the mainstem Columbia River shall be limited to 200,000 yearlings released in April and 1,600,000 sub-yearlings in June.

c. Wells-lineage summer chinook salmon volunteering to the Wells Hatchery trap shall be used as broodstock to effectuate the Wells Hatchery and Turtle Rock artificial propagation programs.

d. The WDFW shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during summer chinook trapping at the hatchery. The WDFW shall carefully handle and immediately release upstream incidentally captured listed spring chinook salmon and steelhead adults that are not intended for use as broodstock in concurrently operated and previously authorized Wells Hatchery listed stock recovery programs. The number of listed salmon and steelhead encountered during summer chinook trapping at the hatchery, and their general condition at release, shall be included in the annual report for the program specified in section 6.

e. All summer chinook salmon yearlings released from the hatcheries shall have adipose fin clips and CWTs to monitor program performance and to allow for monitoring and evaluation of adult salmon contribution levels to other Basin salmon production areas.

f. All sub-yearlings released from Wells Hatchery into the mainstem Columbia River shall have adipose fin clips and CWTs to allow monitoring and evaluation of the artificial propagation program.

g. At least 200,000 of the 1,600,000 sub-yearlings released from Turtle Rock Hatchery (the equivalent of a 12.5% marking rate) shall have adipose fin clips and CWTs. Monitoring and evaluation results shall be included in the annual report.

5. *Mainstem Columbia River* - Priest Rapids Fall Chinook Salmon Program

a. The annual production of fall chinook salmon for on-station release from Priest Rapids Hatchery shall be limited to 6,700,000 sub-yearlings, released in June.

b. Fall chinook salmon adults volunteering to the Priest Rapids Hatchery trap shall be utilized as the primary means for obtaining broodstock for the Priest Rapids artificial propagation program.

c. The WDFW shall monitor the incidence of, and minimize capture, holding, and handling effects on, listed salmon and steelhead encountered during fall chinook adult capture activities at the hatchery. The WDFW shall carefully handle and immediately release upstream incidentally captured listed spring chinook salmon and steelhead adults that are collected at Priest Rapids Hatchery. The number of listed

salmon and steelhead encountered during fall chinook adult capture activities at the hatchery, and their general condition at release, shall be included in the annual report for the program specified in section 6.

d. At least 4% (268,000) of the fall chinook salmon juveniles released from the hatchery each year shall have adipose fin clips and CWTs to allow monitoring and evaluation of the artificial propagation program. Monitoring and evaluation results shall be included in the annual report specified below. The proportion of the total annual fish release from Priest Rapids Hatchery that are marked shall be subject to reevaluation through the comprehensive basinwide fish marking initiative proposed through the FCRPS biological opinion.

e. The WDFW shall monitor and report Priest Rapids Hatchery fall chinook salmon contribution to natural spawning in the Hanford Reach, and straying levels to other Columbia River Basin watersheds, including mainstem river reaches upstream of Wanapum Dam. Information regarding contribution to natural spawning and straying to natural areas shall be included in the annual report specified in section 6.

6. *All Programs* - Monitoring and Reporting

a. Broodstock collection protocols shall be developed for all artificial propagation programs addressed in permit 1347 which shall include scheduled trapping dates, trapping times, and collection goals that minimize potential adverse impacts on listed species and incorporate the special conditions listed above. These protocols shall be submitted to NOAA Fisheries by April 15th each year.

b. An annual report for each artificial propagation program shall be prepared that summarizes broodstock trapping activities including capture and disposition of all ESA protected species, spawning, rearing, and release of propagated salmon. Information regarding contribution to natural spawning and straying to natural areas shall be included in the annual report. An annual report of any recreational fishery in the UCR targeting salmon from the permitted programs shall be prepared including estimates of impacts on UCR spring chinook salmon and UCR steelhead.

c. Prior to modification of or deviation from the proposed actions, the permit holders shall notify NOAA Fisheries, Hatchery and Inland Fisheries Branch.

3.0 AFFECTED ENVIRONMENT

The alternatives identified above can potentially affect the physical, biological, economic, and social environments within the proposed action areas. Below is a summary of the major components of the environment and its current baseline condition.

3.1 Physical Environment

The Columbia River is the fourth largest river in North America. Its basin, including its tributaries, covers 258,500 square miles in seven U.S. states and British Columbia. It is the dominant water system in the Pacific Northwest. The Columbia River originates in the Rocky Mountains in British Columbia, flowing over 1,200 miles to enter the ocean near Astoria, Oregon. Major tributaries of the Columbia River in the U.S. are the Kootenai, Clark Fork-Pend Oreille, Snake, and Willamette Rivers.

The Columbia River serves the Pacific Northwest in a number of ways, including navigation, irrigation and other water supply, and electrical power generation. Detailed information on the importance of the river to the region can be found in the NOAA Fisheries FCRPS biological opinion (NMFS 2000).

The Columbia River also has historically produced some of the region's most important and well-known runs of salmon and other anadromous fish. However, it is generally recognized by the scientific community that development – in particular, the construction of hydroelectric projects, including irrigation diversions and urbanization – has radically altered the Columbia River ecosystem to the detriment of Pacific salmon (NRC 1996). Upper Columbia River salmonid populations, including endangered UCR spring chinook salmon and steelhead, have been among the salmon species that have been adversely affected by development. In particular, the construction of Chief Joseph and Grand Coulee Dams prevented thousands of UCR-origin spring chinook salmon and steelhead from reaching their natal streams. Remaining anadromous salmonid populations in the UCR region must traverse at least seven mainstem dams during downstream and upstream migration; Methow River populations must migrate through nine dams. Mortalities occurring at the seven mainstem dams are considered a primary man-caused limiter to spring chinook salmon production (WDF et al. 1993). Local habitat problems related to irrigation diversions, hydroelectric development, urbanization, and livestock grazing also limit the productivity of naturally-produced spring chinook salmon and steelhead in the region (WDFW 1998; NMFS 2000; NMFS 2001). Supplementation and mitigation programs are being implemented because the natural salmonid populations are not replacing themselves. Artificial propagation programs are viewed as an appropriate strategy to mitigate the effects of development and to assist in the recovery of wild fish populations (NMFS 2000).

Artificial propagation actions could temporarily adversely affect water quality through water withdrawals or diversions (from aquifers and streams) to support hatchery facilities. In the long term, some amount of additional fish wastes may enter the streams from rearing and acclimation ponds, but this impact is regulated by existing water quality standards. Effects on water quality related to the presence of salmonid carcasses in the water, as a result of dying after spawning or dying during unsuccessful upstream migration, may occur. The historical amounts of nutrients available to the ecosystem from these carcasses was large, and contributed to the enhancement of many forms of aquatic and terrestrial life, including the organisms juvenile salmon feed upon during rearing. Decomposing carcasses of spawned salmon would have temporary and local effects on water quality as nutrients are dissolved into the stream and taken up by aquatic and terrestrial

flora and fauna. Over-all and long-term effects on water quality resulting from artificial propagation programs are expected to be negligible, and are regulated by existing water quality regulations.

3.2 Biological Environment

The proposed artificial propagation programs are located and implemented within the UCR Basin from the mainstem Columbia River just downstream of Priest Rapids Dam to the extent of anadromous salmon migration in mainstem and tributary areas downstream of Chief Joseph Dam. Biological resources outside of these areas are not likely to be affected.

3.2.1 Fish Species Listed Under the ESA

Since 1991, NOAA Fisheries has identified twelve populations of Columbia River Basin salmon and steelhead as requiring protection under the ESA. Two of the ESA-listed ESUs originate in the UCR Basin. The ESUs expected to be impacted by the artificial propagation programs covered in this EA and their current listing status are described below. Both of the ESA-listed ESUs in the region include natural-origin and artificially propagated components.

UCR Spring-Run Chinook Salmon ESU – listed "endangered" (March 24, 1999, 64 FR 14308). The UCR spring-run chinook salmon ESU includes stream-type spring chinook salmon populations originating from all areas of the Columbia River basin upstream of Rock Island Dam (Myers et al. 1998). Production areas include the Wenatchee, Methow, and Entiat River Basins. WDF et al. (1993) identified nine stocks within this ESU. All stocks, with the exception of the Methow stock, were considered by WDF et al. (1993) to be of native origin, of "wild" production type, and as "depressed" in status. The Methow River spring chinook salmon stock is considered "composite" in production type, but of native origin, and depressed in status. When listing the UCR spring chinook salmon as endangered, NOAA Fisheries included six hatchery populations as part of the ESU: Chiwawa River, Methow River, Twisp River, Chewuch River, White River, and Nason Creek. These six hatchery populations were considered to be essential for recovery and were therefore included in the listing determination. Hatchery populations at Winthrop NFH, Entiat NFH, and Leavenworth NFH were not included as part of the ESU because they were derived from Carson NFH spring chinook salmon.

Spring chinook salmon destined for the UCR and tributaries begin entering the Columbia River in late February and early March. Their abundance downstream from Bonneville Dam peaks in April and early May. Upper Columbia River spring chinook salmon have a stream-type life history. Adults return to the Wenatchee River from late March to early May, and from late March to June in the Entiat and Methow Rivers. Most adults return after spending two years in the ocean, while 20-40 percent return after three years at sea. Peak spawning for all three populations occurs from August to September. Smolts typically spend one year in freshwater before migrating downstream. This ESU has slight genetic differences from other ESUs containing stream-type fish, but more importantly it has ecological differences in spawning and rearing habitats that were used to define the ESU boundary (Myers et al. 1998). The Grand Coulee Fish Maintenance Project (1939-1943)

was also a major influence on this ESU because fish from multiple populations were mixed into one relatively homogenous group and redistributed into streams throughout the UCR Region.

Upper Columbia River Steelhead ESU – listed "endangered" (August 18, 1997, 62 FR 43937). This ESU inhabits the Columbia River and tributaries upstream of the Yakima River. It includes rivers mostly draining the east slope of the Cascade Mountains. This area includes several rivers which originate in Canada, but it is not thought that steelhead ever occurred in Canada in large numbers; this ESU is considered to include only U.S. populations. This entire ESU has been heavily influenced by artificial propagation programs, with a thorough mixing of stocks as a result of the Grand Coulee Fish Maintenance Project beginning in the 1940s (Fish and Hanavan 1948; Mullan et al. 1992). Until very recently, hatchery releases composed of a composite of basin stocks continued. The Wells Hatchery stock is included in the listing. Currently, efforts are underway to develop artificial propagation programs from more locally-adapted stocks, using naturally-spawning fish.

The life history of this ESU is similar to other inland steelhead ESUs. However, smolt ages in this ESU are some of the oldest on the west coast (up to 7 years old), likely as a result of the ubiquitous cold water temperatures (Mullan et al. 1992). Adults of this ESU spawn later than most downstream populations. Adults of Wenatchee and Entiat River populations return after 1 year in the ocean, of the Methow River primarily after 2 years of ocean life. Adults remain in fresh water up to a year before spawning. Steelhead counts at the dams above Bonneville Dam surge as mainstem water temperatures decline in the fall. Counts peak at the UCR dams in August and September. During years of above average September-October flows and lower temperatures, steelhead move readily past the dams on the Columbia River during the summer/fall counting period (July-October).

Bull Trout - Another ESA-listed fish species that could be present in the areas where the hatchery activities are proposed to occur is bull trout. The Columbia River population segment of bull trout was listed as threatened by the U.S. Fish and Wildlife Service in 1997 (June 10, 1998, 63 FR 31647). Bull trout populations are known to exhibit four distinct life history forms: resident, fluvial, adfluvial, and anadromous. Resident bull trout spend their entire life cycle in the same (or nearby) streams in which they were hatched. Fluvial and adfluvial populations spawn in tributary streams where the young rear from 1 to 4 years before migrating to either a lake (adfluvial) system or a river (fluvial) system, where they grow to maturity. Anadromous fish spawn in tributary streams, with major growth and maturation occurring in salt water.

Migratory bull trout have been restricted or eliminated due to stream habitat alterations, including seasonal or permanent obstructions, detrimental changes in water quality, increased temperatures, and the alteration of natural stream flow patterns. The disruption of migratory corridors, if severe enough, would result in the loss of migratory life history types and isolate resident forms from interacting with the metapopulation. The Columbia River population segment encompasses a vast geographic area including portions of Idaho, Montana, Oregon, Washington, and British Columbia. Bull trout are present, and locally common, in most of the habitat occupied by anadromous fish in the UCR Basin.

3.2.2 Unlisted Fish Species

Approximately 60 other species of fish live in the Columbia River and tributaries. About half are native species primarily of the families Salmonidae, Catastomidae, Cyprinidae, and Cottidae. Unlisted white sturgeon, *Acipenser transmontanus,* occur within the action area in the mainstem Columbia River. The Columbia River Basin also supports at least 25 introduced species primarily representing Percidae, Centrarchidae, and Ictaluridae. Most of the introduced species are game fish which may be the targets of fisheries that could incidentally take ESA-listed anadromous salmonids. No measurable positive or negative affects are anticipated on unlisted fish species.

3.2.3 Terrestrial Organisms

Impacts on terrestrial organisms such as beavers, river otters, and other piscivores and scavengers, ESA-listed or unlisted, as a result of the proposed programs are not anticipated to be substantial. The scale of the proposed artificial propagation programs is relatively small given the geographic region, and because the programs make use of existing hatchery facilities for the hatching and rearing stages, and no substantial impact to the riparian habitat is anticipated. Long-term benefits accruing to terrestrial piscivores and scavengers may be important if the projects are successful, with commensurate habitat restoration and fisheries harvest management actions outside the scope of this assessment, in restoring salmon populations to historic abundance levels. Nutrients derived from carcasses of naturally spawning, or out-planted, hatchery-origin salmon would be added to regional watersheds. These carcasses and their nutrients would be utilized naturally, benefitting terrestrial organisms within the watersheds where the artificial propagation programs are located. However, such effects are not expected to be of substantial benefit for some years to come.

3.2.4 Water Quality

Hatchery-related impacts on water quality may potentially occur through activities directly related to holding and spawning of adult salmon, egg incubation, rearing of juvenile salmon, and release of salmon smolts. Section 303(d) of the Federal Clean Water Act administered by the Environmental Protection Agency (EPA) requires states to monitor water quality and prepare a list of waterbodies that fall outside the surface water quality standards set by the EPA. In the UCR basin, the Columbia, Wenatchee, Methow, and Okanogan Rivers, along with various tributaries of those rivers, are on the 1998 303(d) list because water temperatures were above the standard set on at least more than one sampling occasion. The water temperature standard was calculated based on biological tolerances of salmon (*http://www.ecy.wa.gov/programs/wq/swqs/index.html*, as of November 12, 2002). Additionally, low instream flows in the Wenatchee and Methow Basins placed these rivers on the 1998 303(d) list. The Okanogan River Basin also repeatedly exceeded fecal coliform and toxic substance (arsenic and polychlorinated biphenyls) limits when tested in 1988.

3.3 Social and Economic Resources

Salmon are culturally, economically, and symbolically important in the Pacific Northwest. Natural and hatchery-origin salmon continue to play an important role for Native American cultural, religious, subsistence, and commercial purposes in the action area. The current depleted status of listed spring chinook salmon and steelhead populations has severely limited many of the cultural practices and subsistence uses of salmon by the local tribes. There has been a 90% decrease in tribal harvest throughout the Pacific Northwest from about 5 million salmon in 1986 to about 500,000 in 1999 (Frank 2002). Historically, the salmon resources in the UCR basin were critical in the life of the Colville Tribes. The Colville Reservation is bordered by the Columbia River for more miles than any other Indian Reservation in the basin. However, due to endangered stocks and areas blocked by federally-owned hydroelectric projects, and the location of the Reservation at the upper end of adult salmon return migration, fishing opportunities for the members of the Confederated Tribes of Colville Reservation are at best severely limited (CCT 2002).

The poor status of the listed populations has also curtailed economic and cultural benefits for non-Indian recreational fisheries that the salmon resource formerly supported. Columbia River chinook salmon populations were at one time acknowledged to be the largest in the world. Early traders, trappers, and settlers began arriving around 1800. These early immigrants began taking salmon for their own use and consumption, often trading for fish with local Indian tribes. Early attempts at commercial taking of salmon began in 1829, with salmon harvest as a commercial industry beginning in earnest by the mid-1880s. The first cannery on the Columbia River produced its first pack of canned salmon in 1866. By 1887, the number of canneries in the basin peaked at 39. Salting, mild-curing, and other methods of salmon preparation were also taking place, and Columbia River salmon were becoming well-known internationally. The total production of canned, mild-cured, and frozen salmon and steelhead in the Columbia River Basin rose from 272,000 pounds in 1886 to annual productions between 20 and 50 million pounds from 1874 through 1936.

The gear used to fish commercially for Columbia River salmon included gill nets, purse seines, traps, dip nets, fish wheels, and a variety of other methods (Craig and Hacker 1940). The combined gear types were landing an average of nearly 24.5 million pounds of salmon and steelhead annually between 1927 and 1934. The increased use of gasoline engines on boats enhanced the development of trolling as a commercial salmon harvest method after about 1905, predominantly for chinook and coho salmon. Between 1926 and 1934, the average annual troll catch of Columbia River salmon was 894,000 pounds of chinook and 2.6 million pounds of coho salmon. Currently, harvest is not considered to be as great a source of salmonid population decrease as habitat degradation and hydropower projects. Harvest rates are managed at conservative levels until improvements in other sectors of the environment are able to take effect.

In the early 1900s, increased agriculture, industry, and land development began to reduce the amount of suitable habitat for salmon spawning and rearing. In that period, the annual catch of chinook salmon fluctuated widely. As chinook salmon abundances began to decline, starting around 1911, the focus of commercial harvest operations began to shift more to other species. As

total salmonid abundances in Columbia River fisheries continued to decline, concerns for the continued health of salmonid stocks increased. Management actions began to be developed and implemented to slow the decline of salmon abundances, including the elimination of fish wheels and purse seines on the Columbia River, and reduced commercial gillnet seasons.

The current status of the salmon populations has also required land and water use restrictions, which have adversely affected uses of local resources by landowners and local industries within the action area. For example, in the Methow River basin irrigation water withdraws have been shut down to protect listed fish. In recent years, with severely reduced salmonid numbers due primarily to habitat degradation and hydropower development in the mainstem river, commercial and recreational fisheries have been considerably curtailed from earlier levels.

Numerous jobs are indirectly (e.g., commercial fishers and retailers) and directly (e.g., fish culturists and fish managers/regulators) associated with or affected by the proposed unlisted salmon artificial propagation programs and the listing of the species under the ESA. Historically, artificial propagation efforts have had a substantial impact on salmon populations in the UCR region. These efforts included hatchery-based enhancement and the extensive trapping and transportation activities associated with the Grand Coulee Fish Maintenance Project (1939-1943), which was intended to mitigate the effects of dam construction and habitat loss by aiding depressed salmon stocks. Many artificial propagation efforts now focus on enhancing naturally spawning salmonid populations to encourage stock recovery and sustainability. In addition to their role in maintaining the viability of salmonid populations, the unlisted salmon artificial propagation programs provide equitable access of all citizens to recreational, commercial, and tribal fisheries throughout the Columbia River Basin in high adult return years.

Similar to rural areas across the country, the local economy of the UCR region has experienced a downturn brought on by many factors. The reductions of fishing opportunities has added to the economic slowdown in the local economy. It was estimated that salmon and steelhead recreational fishing in 1986 had an average value of $34 per trip (USACE). The average number of angler trips to the UCR region was estimated at between 1,500 and 3,000 annually, therefore the economic impact may be about $51,000 to $102,000 annually (1986 dollars).

4.0 ENVIRONMENTAL CONSEQUENCES

This section of the assessment evaluates the potential effects of the alternatives (including the proposed action) on biological, physical, social, and economic resources. NOAA Fisheries' approval or denial of the permit for the unlisted salmon artificial propagation programs could indirectly affect a variety of natural and human resources. Because many of the conditions described in the proposed action were addressed in the Conservation Plan and the HGMPs submitted for the artificial propagation programs, environmental consequences are expected to be similar for Alternatives 2 and 3. However, the environmental consequences resulting from Alternative 1 (No Action) are expected to differ somewhat from the proposed action.

4.1 Alternative One (No Action)

If permit 1347 is not issued, then none of the proposed artificial propagation programs that take listed species would be implemented. The environmental impacts related to the No Action alternative based on this assumption are identified in the following sections.

4.1.1 Effects on the Physical Environment

Termination of the artificial propagation programs would not have much effect on the physical environment in the action area. Riparian areas that may serve as access point to traps and juvenile fish release sites would still be utilized for artificial propagation programs of ESA-listed spring chinook and steelhead (authorized under permits 1196, 1248, 1300). While hatchery effluent would not be released from some of the facilities that rear only the unlisted species, other facilities would release effluent associated with ESA-listed species propagation authorized under other permits. The Wenatchee, Methow, Okanogan, and Columbia Rivers have temperatures above the optimal conditions for salmon as indicated by their inclusion on the EPA's 1998 303(b) list and this would not change due to curtailment of these programs.

4.1.2 Effects on the Biological Environment

Effects on ESA-listed Anadromous Fish
Under the "No Action" alternative, ESA-listed anadromous fish would not be exposed to risks of injury or mortality as a result of broodstock collection, juvenile fish release, or research and monitoring and evaluation actions occurring through the unlisted salmon artificial propagation programs. The complete curtailment of the unlisted salmon artificial propagation programs in the UCR region may result in a slight increase in escapements for listed salmonid populations. The amount of increase would be equal to or slightly less than the number of adults dying, debilitated, or otherwise rendered unable to spawn as a result of handling during broodstock collection activities. The potential increase in escapements is nearly impossible to estimate and the gain from such an action would not measurably benefit the conservation of ESA-listed salmon and steelhead.

Under the "No Action" alternative, the impacts on listed bull trout would be the same as under Alternatives 2 and 3. The artificial propagation programs are implemented in areas where bull trout are either not encountered, or occur at such low numbers that effects would be negligible.

Effects on Non-listed Target Anadromous Fish Species
The propagation programs considered in the proposed permit are designed to enhance the natural populations by returning adults to the spawning grounds. If the unlisted salmon artificial propagation programs are not implemented, beneficial prey sources (juvenile hatchery fish) and nutrients (hatchery-origin salmon carcasses) made available by the programs to natural population of the target species would no longer exist, though other prey and nutrients sources are present.

Effects on Non-listed Non-Target Anadromous Fish Species
No substantial effects of the No Action alternative are anticipated to occur on fish species not

targets of the artificial propagation program or listed under the ESA. If the unlisted salmon artificial propagation programs are not implemented, beneficial prey sources (juvenile hatchery fish) and nutrients (hatchery-origin salmon carcasses) made available by the programs to non-listed fish species in the region would no longer exist, though other prey and nutrients sources are present.

Effects on Terrestrial Organisms
No substantial effects of the No Action alternative are anticipated to occur on listed or unlisted terrestrial organisms. If the unlisted salmon artificial propagation programs are not implemented, beneficial prey sources (juvenile and adult hatchery fish) and nutrients (hatchery-origin salmon carcasses) made available by the programs to terrestrial species in the region would no longer exist. This is probably a negligible source of nutrition for terrestrial organisms.

4.1.3 Effects on the Social and Economic Resources

The "No Action" alternative would result in economic losses to local fishermen and communities, and in reductions in opportunities for Native American subsistence and cultural uses of salmon, within the UCR Basin. Surplus unlisted salmon produced by the programs for harvest in Native American and non-Indian fisheries would no longer be available. Fishery closures to protect ESA-listed anadromous salmonids from harvest have already occurred to a considerable extent, affecting commercial, recreational, and tribal fishers. Eliminating unlisted salmon production in the action area would also likely lead to curtailment of the last anadromous salmon fishery opportunities in this area. It was estimated that salmon and steelhead sport fishing in 1986 had an average value of $34 per trip (USACE 1999). During the summer chinook salmon season, between 1,500 and 3,000 angler trips may occur in the UCR Basin, therefore the economic impact could be the loss of about $51,000 to $102,000 annually (1986 dollars) to the local UCR region. Annual salmon harvest activities throughout the Columbia River basin are negotiated annually to minimize adverse effects on listed fish while still

providing fishery harvest opportunity. This alternative would also reduce local public support of conservation and recovery efforts because of the loss of local fishery benefits.

4.2 Alternative Two (Issue Permit Without Conditions)

The purpose of permit conditions is to prescribe requirements and/or restrictions that are expressly designed to minimize impacts on ESA-listed fish. Issuing permits and permit modifications to agencies without conditions would result in many of the same environmental impacts described in the proposed action alternative below because many of the techniques that result in permit conditions are provided as proposed strategies in permit applications. However, not imposing conditions in permits could potentially result in unexpected environmental impacts if strategies designed to minimize adverse impacts are significantly altered by the Permit Holder. Establishing conditions in permits ensures that measures would be implemented by the Permit Holder to minimize adverse impacts on ESA-listed fish and that agency actions would not appreciably reduce the survival and recovery of ESA-listed species. In addition, NOAA Fisheries' conditions may serve to further limit the proposed activities in such a way as to enhance the proposed conservation

efforts, as described in section 4.3, below.

4.3 Alternative Three (Proposed Action)

If permit 1347 is issued, then actions described in the conservation plan, HGMPs, and HCPs would be implemented with specific conservation recommendations, limits and reporting requirements.

4.3.1 Effects on the Physical Environment

The effects on the physical environment resulting from implementation of the proposed artificial propagation programs would include impacts on small areas of riparian vegetation and habitat during the operation of unlisted broodstock trapping, fish rearing, and fish acclimation and release facilities. The hatchery facilities, traps, and acclimation ponds are already in place and their operation would result in small effects on the physical environment. Possible impacts include walking through riparian areas to access traps and release juvenile fish. Such impacts would be minimal and short lived. Water quantity and quality could be minimally adversely affected. To limit impacts on water quantity, the action agencies would comply with water right permits established for each hatchery to prevent over-appropriation of surface water and/or rely on ground water withdrawal.

Water quality is minimally affected by effluent from the hatcheries, which would be monitored to ensure compliance with NPDES water quality standards. The water source for many of the hatchery facilities is pathogen-free well water. The water quality of hatchery effluent from a well water source is likely to be higher than many of the rivers the effluent is released into. Facilities that utilize surface water would apply measures such as settling ponds to remove settleable solids to ensure effluent does not exceed NPDES standards. Hatchery effluent from facilities that utilize well water would be released at a lower temperature than the ambient river temperature during summer and early fall months when the ambient river temperature exceeds EPA section 303(b) standards; therefore, if any impact is realized it would be a positive impact. Considering that the effluent produced from the hatchery facilities often originates from pathogen-, and contaminant-free well water, complies with EPA standards, and comprises a low percentage of effluent to discharge (dilution factor), there is a low possibility that effluent produced at these facilities would negatively impact the physical environment and any impact is likely to be minimal.

Impacts on Habitat
Impact of these activities on the habitat of the ESA-listed species is expected to be minor or non-existent. The WDFW, or the Chelan PUD and Douglas PUD funding the operations, retain water withdrawal permits issued by Washington Department of Ecology for ground and surface water used in the hatchery operations. Compliance with permit requirements ensures that the artificial propagation programs do not over-appropriate surface water to the detriment of adjacent water courses serving as aquatic habitat. Hatchery effluents currently meet NPDES permit requirements and would continue to do so, minimizing the likelihood of adverse effects on listed salmon and steelhead in the upper Columbia tributary areas. Dilution factors in the UCR mainstem migration corridor further reduce the likelihood of any adverse effects on listed salmon and steelhead

populations in the mainstem river.

4.3.2 Effects on the Biological Environment

Effects on ESA-listed Fish
Impacts on listed UCR fish species resulting from the proposed unlisted salmon artificial propagation programs may result from incidental capture and handling of adult fish during broodstock collection operations, and incidental injury or mortality resulting from encounters with liberated juvenile hatchery fish in the natural environment. The precise level of incidental take of listed salmon and steelhead resulting from and juvenile salmon releases in the mid and upper-Columbia River regions is unknown. Quantification of mortality levels of juvenile listed salmon and steelhead is not possible, due to the inherent biological characteristics of the listed fish, the scale and variability of the Columbia Basin river systems, and the operational complexity of the subject hatchery actions. The WDFW believes that the minimization actions directed towards wild salmon and steelhead protection implemented in upper-river major hatchery operations, including release practices and smolt-only releases, will lead to insignificant levels of incidental take. Broodstock collection activities are likely to encounter few ESA-listed spring chinook **SALMON BECAUSE OF MIGRATION TIMING DIFFERENCES BETWEEN THE SPECIES. STEELHEAD ENCOUNTERED DURING UNLISTED SPECIES BROODSTOCK COLLECTION ACTIVITIES ARE REGULARLY RETAINED AS BROODSTOCK FOR ESA-LISTED ARTIFICIAL PROPAGATION PROGRAMS.**

Effects on Unlisted Fish Species
The proposed artificial propagation programs would be implemented to supplement natural salmon populations in the UCR region. The WDFW applies appropriate broodstock collection, mating, and juvenile fish production procedures to ensure that adult fish produced through the programs are representative of the target natural-origin populations. The programs are designed to preserve the ecological and genetic characteristics of the supplemented populations, while increasing the abundance of adult returns to the region.

Unlisted fish species in the action area would be expected to benefit from nutrient enrichment provided by hatchery fish carcasses in stream reaches used by the species. The potential to utilize the marine-based nutrients that are imported to freshwater ecosystems in the carcasses of hatchery returns may be of value for stimulating ecosystem recovery. Experiments have shown that carcasses of hatchery-produced salmon can be an important source of nutrients for juvenile salmon rearing in streams (Bilby *et al.* 1998). Juvenile fish released by the hatcheries also are likely to benefit unlisted fish species as prey.

Adverse ecological effects on unlisted fish are minimized through the release of actively smolting fish from the artificial propagation programs. The hatchery smolts migrate seaward rapidly after release, limiting the duration of interaction, and opportunity for adverse ecological effects, on co-occurring unlisted fish species. The Wenatchee sockeye salmon are released during the fall and rear through the winter months in the lake. Winter activity is expected to be low because of reduced metabolic rates associated with low water temperatures.

Effects on Terrestrial Organisms
Juvenile fish releases and adult salmon returns resulting from the programs would make additional fish (live or as carcasses) available for use by terrestrial organisms. The potential to utilize the marine-based nutrients that are imported to freshwater ecosystems in the carcasses of hatchery returns may be of value for stimulating ecosystem recovery. Hatchery carcasses may replace some of the nutrient deficit in riparian plant and terrestrial wildlife communities where naturally produced spawners are lacking (Bilby *et al.* 1998). In the context of the entire geographic area, the nutrient input that would occur is small and limited by actions outside the scope of this EA, such as habitat improvement and restoration projects.

4.3.3 Effects on Social and Economic Resources

This alternative would likely result in beneficial effects on local communities. If a permit is issued authorizing the proposed unlisted salmon artificial propagation programs, economic, cultural, and aesthetic benefits would accrue to the human population within the UCR region. The programs would help contribute to self-sustaining salmon populations, and to the availability of fish for harvest in Native American and non-Indian fisheries. The availability of salmon for ceremonial and subsistence and commercial uses by the treaty Indian tribes would increase.

Non-Indian commercial and recreational fisheries accessing adult fish production from the hatcheries provide substantial income and important employment opportunities in remote, rural communities located in the Columbia River Basin. Revenue would be generated from the sale of adult salmon, fishing licenses, fishing equipment, lodging and food. It was estimated that salmon and steelhead sport fishing in 1986 had an average value of $34 per trip (USACE 1999). During the summer chinook season between 1,500 and 3,000 angler trips may occur in the UCR Basin, therefore the economic impact may be about $51,000 to $102,000 annually (1986 dollars). By assisting in increasing abundances of adult unlisted salmon, this alternative would also maintain local public support of salmon and steelhead recovery efforts because of the local economic benefits associated with these programs. The potential benefits of the proposed activities would be accessible to all citizens and not pose a disproportionate adverse impact on minority or low-income populations.

4.3.4 Cumulative Impacts

Cumulative impacts from NOAA Fisheries' proposed issuance of a section 10(a)(1)(B) permit, including additional special conditions as described, will be minor if at all measurable. Incremental impacts on the environment are included in the discussion above. NOAA Fisheries' permitting of the described activities is only one element of a large suite of regulations and environmental factors that may influence the overall management of artificial propagation actions in the affected environment, and that may impact the health of listed salmon populations and their habitat. Those programs that meet the requirements of section 10 and its implementing regulations will include monitoring and adaptive management measures so that basin co-managers can respond to changes in the status of affected listed salmon. Monitoring and adaptive management will help ensure that

the affected ESUs are adequately protected and help counter-balance any negative cumulative impacts.

7.0 FINDING OF NO SIGNIFICANT IMPACT

Summary

The National Marine Fisheries Service (NOAA Fisheries) Northwest Region (NWR) has prepared an Environmental Assessment (EA) of its proposed issuance of a permit pursuant to section 10(a)(1)(B) of the Endangered Species Act (ESA). The permit (#1347) would be issued jointly to the Washington Department of Fish and Wildlife (WDFW), Public Utility District No. 1 of Chelan County (Chelan PUD), and Public Utility District No. 1 of Douglas County (Douglas PUD) for annual take of ESA-listed Upper Columbia River (UCR) spring chinook and UCR steelhead incidental to operation of the artificial propagation programs rearing unlisted species in the Upper Columbia River. The permit would expire December 31, 2013.

NOAA Fisheries considered and analyzed the following alternatives, all of which are discussed in detail in the EA:

> Alternative 1 - No Action: Do not issue the permit, which would likely require WDFW, Chelan PUD, and Douglas PUD to cease, or drastically reduce the scope of, the programs.
>
> Alternative 2 - Issue the permit based on the application without any additional specific conditions.
>
> Alternative 3 - Proposed Action: Issue the permit based on the application with additional specific conditions to minimize adverse impacts on the ESA listed salmonids and to enhance conservation efforts.

The proposed action would allow the permit holders to implement artificial production programs that are designed to enhance natural production of salmonid species and provide fishery opportunity while still remaining consistent with recovery of ESA listed endangered UCR spring chinook salmon and UCR steelhead in the Wenatchee, Methow, and Okanogan River Basins in the state of Washington. The programs are fully described in the EA and in the permit application documents (the Conservation Plan, three Hatchery Genetic Management Plans, and three Habitat Conservation Plans).

Issuance of the permit with additional special conditions would be expected to result in the following environmental, social, and economic effects:

- Small, localized, and transitory adverse effects on water quantity and water quality from water withdrawals and hatchery effluent.
- Potential deleterious effects from artificial propagation such as maladaptive genetic, physiological and behavioral changes, disease transmission and reduction in the number of adults spawning in the wild.
- Few, if any, effects on other ESA-listed species through trapping activities that have the potential to handle listed spring chinook, steelhead, and bull trout.

- Benefits to listed fish and other resident species from recycled marine nutrients added to the ecosystem.
- Restoration of non-consumptive observation of spawning salmon and existence values.
- Mitigation for continued impacts from the hydro-power system where impacts cannot be minimized through design and operational changes.
- Increased availability of salmon for ceremonial and subsistence uses by treaty tribes and the opportunity for recreational fisheries.

These are fully described in the EA.

In the EA, NOAA Fisheries considered the context and intensity of the factors identified in NOAA NAO 216-6 section 6.01b, as well as short and long term effects of the proposed action. Based on the analysis in the EA, NOAA Fisheries finds that:

1. Public health and safety will be minimally affected by the preferred alternative. Any degradation of water quality will be restricted to the areas immediately adjacent to hatchery water discharges, and any adverse effects will be localized and temporary.

2. The proposed action alternative effects on the human environment are not likely to be highly controversial based on information provided during the public comment period and the low level of adverse impact on socioeconomic resources expected (as described in the EA).

3. This action does not establish a precedent for future actions with significant effects nor does it represent a decision in principle about a future consideration because NOAA Fisheries has analyzed many comparable programs and issued many comparable permits.

4. This action is of limited context and intensity, with limited environmental effects, individually or cumulatively.

5. The effects of this action are relatively certain and do not involve unique or unknown risks because this artificial propagation program is similar to other artificial propagation programs designed to provide fish for harvest and enhance natural production while still ensuring conservation of protected populations that NOAA Fisheries has considered and authorized.

6. The proposed action will not adversely affect areas listed in or eligible for listing in the National Register of Historic Places, or cause loss or destruction of significant scientific, cultural or historic resources.

7. ESA-listed endangered UCR spring chinook salmon and steelhead will be adversely affected by the proposed action. However, based on NOAA Fisheries' evaluation, the proposed action will have only relatively small impacts on non-target species.

8. The proposed action will not adversely modify or destroy designated critical habitat as defined by the ESA or designated essential fish habitat (EFH) as defined by the Magnuson-Stevens Act. The artificial propagation programs that are the subject of the proposed action will affect habitat features such as water quality, water quantity, adult passage impediment, predation, competition, and exchange of disease organisms. As discussed in the EA, any adverse effects will by minimal, localized and temporary. The proposed permit conditions and operating procedures are designed to minimize the adverse effects.

9. The proposed action does not threaten a violation of federal, state, or local law requirements imposed for the protection of the environment. To comply with water quality standards, hatchery operators must obtain National Pollutant Discharge Elimination System (NPDES) permits this requirement is included in the application.

Environmental Justice: Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*. The analysis of the impacts in the EA indicates that there will be no disproportionately high and adverse environmental impacts, as described in the executive order, on minority and low-income populations by the proposed action.

Determination

Based on the analysis in the EA, I conclude that the proposed action to issue permit #1347 with specific conditions to WDFW, Chelan PUD, and Douglas PUD pursuant to section 10(a)(1)(B) of the ESA does not constitute a major Federal action significantly affecting the quality of the human environment within the meaning of section 102(2)(c) of the National Environmental Policy Act of 1969 (as amended). Therefore, an environmental impact statement is not required.
